File Names, Command Line Arguments, and Environment Variables

In Python, file names, command line arguments, and environment variables are represented using the string type. On some systems, decoding these strings to and from bytes is necessary before passing them to the operating system. Python uses the filesystem encoding and error handler to perform this conversion (see **sys.getfilesystemencoding()**).

The filesystem encoding and error handler are configured at Python startup by the **PyConfig_Read()** function: see

filesystem_encoding and **filesystem_errors** members of **PyConfig**.

Changed in version 3.1: On some systems, conversion using the file system encoding may fail. In this case, Python uses the surrogateescape encoding error handler, which means that undecodable bytes are replaced by a Unicode character U+DCxx on decoding, and these are again translated to the original byte on encoding.

The file system encoding must guarantee to successfully decode all bytes below 128. If the file system encoding fails to provide this guarantee, API functions can raise **UnicodeError**.

See also the locale encoding.

Python UTF-8 Mode

New in version 3.7: See **PEP 540** [https://peps.python.org/pep-0540/] for more details.

The Python UTF-8 Mode ignores the locale encoding and forces the usage of the UTF-8 encoding:

- Use UTF-8 as the filesystem encoding.
- **sys.getfilesystemencoding()** returns `'utf-8'`.
- **locale.getpreferredencoding()** returns `'utf-8'` (the *do_setlocale* argument has no effect).
- **sys.stdin**, **sys.stdout**, and **sys.stderr** all use UTF-8 as their text encoding, with the `surrogateescape` error handler being enabled for **sys.stdin** and **sys.stdout** (**sys.stderr** continues to use `backslashreplace` as it does in the default locale-aware mode)
- On Unix, **os.device_encoding()** returns `'utf-8'` rather than the device encoding.

Note that the standard stream settings in UTF-8 mode can be overridden by **PYTHONIOENCODING** (just as they can be in the default locale-aware mode).

As a consequence of the changes in those lower level APIs, other

higher level APIs also exhibit different default behaviours:

- Command line arguments, environment variables and filenames are decoded to text using the UTF-8 encoding.
- **`os.fsdecode()`** and **`os.fsencode()`** use the UTF-8 encoding.
- **`open()`**, **`io.open()`**, and **`codecs.open()`** use the UTF-8 encoding by default. However, they still use the strict error handler by default so that attempting to open a binary file in text mode is likely to raise an exception rather than producing nonsense data.

The Python UTF-8 Mode is enabled if the LC_CTYPE locale is `C` or `POSIX` at Python startup (see the **`PyConfig_Read()`** function).

It can be enabled or disabled using the **`-X utf8`** command line option and the **`PYTHONUTF8`** environment variable.

If the **`PYTHONUTF8`** environment variable is not set at all, then the interpreter defaults to using the current locale settings, *unless* the current locale is identified as a legacy ASCII-based locale (as described for **`PYTHONCOERCECLOCALE`**), and locale coercion is either disabled or fails. In such legacy locales, the interpreter will default to enabling UTF-8 mode unless explicitly instructed not to do so.

The Python UTF-8 Mode can only be enabled at the Python startup. Its value can be read from **`sys.flags.utf8_mode`**.

See also the UTF-8 mode on Windows and the filesystem encoding and error handler.

See also

PEP 686 **[https://peps.python.org/pep-0686/]**
Python 3.15 will make Python UTF-8 Mode default.

Process Parameters

These functions and data items provide information and operate on

the current process and user.

os.ctermid()

Return the filename corresponding to the controlling terminal of the process.

Availability: Unix, not Emscripten, not WASI.

os.environ

A mapping object where keys and values are strings that represent the process environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the **`os`** module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in **`os.environ`**, except for changes made by modifying **`os.environ`** directly.

This mapping may be used to modify the environment as well as query the environment. **`putenv()`** will be called automatically when the mapping is modified.

On Unix, keys and values use **`sys.getfilesystemencoding()`** and `'surrogateescape'` error handler. Use **`environb`** if you would like to use a different encoding.

Note

Calling **`putenv()`** directly does not change **`os.environ`**, so it's better to modify **`os.environ`**.

Note

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for **`putenv()`**.

You can delete items in this mapping to unset environment variables. **unsetenv()** will be called automatically when an item is deleted from **os.environ**, and when one of the **pop()** or **clear()** methods is called.

Changed in version 3.9: Updated to support **PEP 584** [https://peps.python.org/pep-0584/]'s merge (|) and update (|=) operators.

os.environb

Bytes version of **environ**: a mapping object where both keys and values are **bytes** objects representing the process environment. **environ** and **environb** are synchronized (modifying **environb** updates **environ**, and vice versa).

environb is only available if **supports_bytes_environ** is `True`.

New in version 3.2.

Changed in version 3.9: Updated to support **PEP 584** [https://peps.python.org/pep-0584/]'s merge (|) and update (|=) operators.

os.chdir(*path*)

os.fchdir(*fd*)

os.getcwd()

These functions are described in Files and Directories.

os.fsencode(*filename*)

Encode path-like *filename* to the filesystem encoding and error handler; return **bytes** unchanged.

fsdecode() is the reverse function.

New in version 3.2.

Changed in version 3.6: Support added to accept objects implementing the **os.PathLike** interface.

os.fsdecode(*filename*)

Decode the path-like *filename* from the filesystem encoding and error handler; return `str` unchanged.

`fsencode()` is the reverse function.

New in version 3.2.

Changed in version 3.6: Support added to accept objects implementing the `os.PathLike` interface.

os.fspath(*path*)

Return the file system representation of the path.

If `str` or `bytes` is passed in, it is returned unchanged. Otherwise `__fspath__()` is called and its value is returned as long as it is a `str` or `bytes` object. In all other cases, `TypeError` is raised.

New in version 3.6.

class os.PathLike

An abstract base class for objects representing a file system path, e.g. `pathlib.PurePath`.

New in version 3.6.

abstractmethod _fspath_()

Return the file system path representation of the object.

The method should only return a `str` or `bytes` object, with the preference being for `str`.

os.getenv(*key*, *default*=*None*)

Return the value of the environment variable *key* as a string if it exists, or *default* if it doesn't. *key* is a string. Note that since `getenv()` uses `os.environ`, the mapping of `getenv()` is similarly also captured on import, and the function may not reflect future environment changes.

On Unix, keys and values are decoded with **`sys.getfilesystemencoding()`** and `'surrogateescape'` error handler. Use **`os.getenvb()`** if you would like to use a different encoding.

Availability: Unix, Windows.

os.getenvb(*key*, *default*=*None*)

Return the value of the environment variable *key* as bytes if it exists, or *default* if it doesn't. *key* must be bytes. Note that since **`getenvb()`** uses **`os.environb`**, the mapping of **`getenvb()`** is similarly also captured on import, and the function may not reflect future environment changes.

`getenvb()` is only available if **`supports_bytes_environ`** is `True`.

Availability: Unix.

New in version 3.2.

os.get_exec_path(*env*=*None*)

Returns the list of directories that will be searched for a named executable, similar to a shell, when launching a process. *env*, when specified, should be an environment variable dictionary to lookup the PATH in. By default, when *env* is `None`, **`environ`** is used.

New in version 3.2.

os.getegid()

Return the effective group id of the current process. This corresponds to the "set id" bit on the file being executed in the current process.

Availability: Unix, not Emscripten, not WASI.

os.geteuid()

Return the current process's effective user id.

Availability: Unix, not Emscripten, not WASI.

os.getgid()

Return the real group id of the current process.

Availability: Unix.

The function is a stub on Emscripten and WASI, see WebAssembly platforms for more information.

os.getgrouplist(*user*, *group*, */*)

Return list of group ids that *user* belongs to. If *group* is not in the list, it is included; typically, *group* is specified as the group ID field from the password record for *user*, because that group ID will otherwise be potentially omitted.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.getgroups()

Return list of supplemental group ids associated with the current process.

Availability: Unix, not Emscripten, not WASI.

Note

On macOS, `getgroups()` behavior differs somewhat from other Unix platforms. If the Python interpreter was built with a deployment target of `10.5` or earlier, `getgroups()` returns the list of effective group ids associated with the current user process; this list is limited to a system-defined number of entries, typically 16, and may be modified by calls to `setgroups()` if suitably privileged. If built with a deployment target greater than `10.5`, `getgroups()` returns the current group access list for the user associated with the effective user id of the process; the group access list may change over the lifetime

of the process, it is not affected by calls to **setgroups()**, and its length is not limited to 16. The deployment target value, **MACOSX_DEPLOYMENT_TARGET**, can be obtained with **sysconfig.get_config_var()**.

os.getlogin()

Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use **getpass.getuser()** since the latter checks the environment variables **LOGNAME** or **USERNAME** to find out who the user is, and falls back to `pwd.getpwuid(os.getuid())[0]` to get the login name of the current real user id.

Availability: Unix, Windows, not Emscripten, not WASI.

os.getpgid(*pid*)

Return the process group id of the process with process id *pid*. If *pid* is 0, the process group id of the current process is returned.

Availability: Unix, not Emscripten, not WASI.

os.getpgrp()

Return the id of the current process group.

Availability: Unix, not Emscripten, not WASI.

os.getpid()

Return the current process id.

The function is a stub on Emscripten and WASI, see WebAssembly platforms for more information.

os.getppid()

Return the parent's process id. When the parent process has

exited, on Unix the id returned is the one of the init process (1), on Windows it is still the same id, which may be already reused by another process.

Availability: Unix, Windows, not Emscripten, not WASI.

Changed in version 3.2: Added support for Windows.

os.getpriority(*which*, *who*)

Get program scheduling priority. The value *which* is one of **PRIO_PROCESS**, **PRIO_PGRP**, or **PRIO_USER**, and *who* is interpreted relative to *which* (a process identifier for **PRIO_PROCESS**, process group identifier for **PRIO_PGRP**, and a user ID for **PRIO_USER**). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.PRIO_PROCESS
os.PRIO_PGRP
os.PRIO_USER

Parameters for the **getpriority()** and **setpriority()** functions.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.getresuid()

Return a tuple (ruid, euid, suid) denoting the current process's real, effective, and saved user ids.

Availability: Unix, not Emscripten, not WASI.

New in version 3.2.

os.getresgid()

Return a tuple (rgid, egid, sgid) denoting the current process's real, effective, and saved group ids.

Availability: Unix, not Emscripten, not WASI.

New in version 3.2.

os.getuid()

Return the current process's real user id.

Availability: Unix.

The function is a stub on Emscripten and WASI, see WebAssembly platforms for more information.

os.initgroups(*username*, *gid*, */*)

Call the system initgroups() to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

Availability: Unix, not Emscripten, not WASI.

New in version 3.2.

os.putenv(*key*, *value*, */*)

Set the environment variable named *key* to the string *value*. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

Assignments to items in `os.environ` are automatically translated into corresponding calls to `putenv()`; however, calls to `putenv()` don't update `os.environ`, so it is actually preferable to assign to items of `os.environ`. This also applies to `getenv()` and `getenvb()`, which respectively use `os.environ` and `os.environb` in their implementations.

Note

On some platforms, including FreeBSD and macOS, setting `environ` may cause memory leaks. Refer to the system documentation for **`putenv()`**.

Raises an auditing event `os.putenv` with arguments `key`, `value`.

Changed in version 3.9: The function is now always available.

os.setegid(*egid*, */*)

Set the current process's effective group id.

Availability: Unix, not Emscripten, not WASI.

os.seteuid(*euid*, */*)

Set the current process's effective user id.

Availability: Unix, not Emscripten, not WASI.

os.setgid(*gid*, */*)

Set the current process' group id.

Availability: Unix, not Emscripten, not WASI.

os.setgroups(*groups*, */*)

Set the list of supplemental group ids associated with the current process to *groups*. *groups* must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

Availability: Unix, not Emscripten, not WASI.

Note

On macOS, the length of *groups* may not exceed the system-defined maximum number of effective group ids, typically 16. See the documentation for **`getgroups()`** for

cases where it may not return the same group list set by calling setgroups().

os.setpgrp()

Call the system call **`setpgrp()`** or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

Availability: Unix, not Emscripten, not WASI.

os.setpgid(*pid*, *pgrp*, /)

Call the system call **`setpgid()`** to set the process group id of the process with id *pid* to the process group with id *pgrp*. See the Unix manual for the semantics.

Availability: Unix, not Emscripten, not WASI.

os.setpriority(*which*, *who*, *priority*)

Set program scheduling priority. The value *which* is one of **`PRIO_PROCESS`**, **`PRIO_PGRP`**, or **`PRIO_USER`**, and *who* is interpreted relative to *which* (a process identifier for **`PRIO_PROCESS`**, process group identifier for **`PRIO_PGRP`**, and a user ID for **`PRIO_USER`**). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process. *priority* is a value in the range -20 to 19. The default priority is 0; lower priorities cause more favorable scheduling.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.setregid(*rgid*, *egid*, /)

Set the current process's real and effective group ids.

Availability: Unix, not Emscripten, not WASI.

os.setresgid(*rgid*, *egid*, *sgid*, */*)

Set the current process's real, effective, and saved group ids.

Availability: Unix, not Emscripten, not WASI.

New in version 3.2.

os.setresuid(*ruid*, *euid*, *suid*, */*)

Set the current process's real, effective, and saved user ids.

Availability: Unix, not Emscripten, not WASI.

New in version 3.2.

os.setreuid(*ruid*, *euid*, */*)

Set the current process's real and effective user ids.

Availability: Unix, not Emscripten, not WASI.

os.getsid(*pid*, */*)

Call the system call **`getsid()`**. See the Unix manual for the semantics.

Availability: Unix, not Emscripten, not WASI.

os.setsid()

Call the system call **`setsid()`**. See the Unix manual for the semantics.

Availability: Unix, not Emscripten, not WASI.

os.setuid(*uid*, */*)

Set the current process's user id.

Availability: Unix, not Emscripten, not WASI.

os.strerror(*code*, */*)

Return the error message corresponding to the error code in *code*. On platforms where **strerror()** returns NULL when given an unknown error number, **ValueError** is raised.

os.supports_bytes_environ

`True` if the native OS type of the environment is bytes (eg. `False` on Windows).

New in version 3.2.

os.umask(*mask*, */*)

Set the current numeric umask and return the previous umask.

The function is a stub on Emscripten and WASI, see WebAssembly platforms for more information.

os.uname()

Returns information identifying the current operating system. The return value is an object with five attributes:

- **sysname** - operating system name
- **nodename** - name of machine on network (implementation-defined)
- **release** - operating system release
- **version** - operating system version
- **machine** - hardware identifier

For backwards compatibility, this object is also iterable, behaving like a five-tuple containing **sysname**, **nodename**, **release**, **version**, and **machine** in that order.

Some systems truncate **nodename** to 8 characters or to the leading component; a better way to get the hostname is **socket.gethostname()** or even `socket.gethostbyaddr(socket.gethostname()).`

Availability: Unix.

Changed in version 3.3: Return type changed from a tuple to a

tuple-like object with named attributes.

os.unsetenv(*key*, */*)

Unset (delete) the environment variable named *key*. Such changes to the environment affect subprocesses started with **os.system()**, **popen()** or **fork()** and **execv()**.

Deletion of items in **os.environ** is automatically translated into a corresponding call to **unsetenv()**; however, calls to **unsetenv()** don't update **os.environ**, so it is actually preferable to delete items of **os.environ**.

Raises an auditing event `os.unsetenv` with argument `key`.

Changed in version 3.9: The function is now always available and is also available on Windows.

File Object Creation

These functions create new file objects. (See also **open()** for opening file descriptors.)

os.fdopen(*fd*, **args*, ***kwargs*)

Return an open file object connected to the file descriptor *fd*. This is an alias of the **open()** built-in function and accepts the same arguments. The only difference is that the first argument of **fdopen()** must always be an integer.

File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name "file descriptor" is slightly deceptive; on

Unix platforms, sockets and pipes are also referenced by file descriptors.

The `fileno()` method can be used to obtain the file descriptor associated with a file object when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

os.close(*fd*)

Close file descriptor *fd*.

Note

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To close a "file object" returned by the built-in function `open()` or by `popen()` or `fdopen()`, use its `close()` method.

os.closerange(*fd_low*, *fd_high*, */*)

Close all file descriptors from *fd_low* (inclusive) to *fd_high* (exclusive), ignoring errors. Equivalent to (but much faster than):

```
for fd in range(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

os.copy_file_range(*src*, *dst*, *count*, *offset_src=None*, *offset_dst=None*)

Copy *count* bytes from file descriptor *src*, starting from offset *offset_src*, to file descriptor *dst*, starting from offset *offset_dst*. If *offset_src* is None, then *src* is read from the current position; respectively for *offset_dst*. The files pointed by *src* and *dst* must reside in the same filesystem, otherwise an `OSError` is raised with `errno` set to `errno.EXDEV`.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations. The copy is done as if both files are opened as binary.

The return value is the amount of bytes copied. This could be less than the amount requested.

Availability: Linux >= 4.5 with glibc >= 2.27.

New in version 3.8.

os.device_encoding(*fd*)

Return a string describing the encoding of the device associated with *fd* if it is connected to a terminal; else return **None**.

On Unix, if the Python UTF-8 Mode is enabled, return `'UTF-8'` rather than the device encoding.

Changed in version 3.10: On Unix, the function now implements the Python UTF-8 Mode.

os.dup(*fd*, */*)

Return a duplicate of file descriptor *fd*. The new file descriptor is non-inheritable.

On Windows, when duplicating a standard stream (0: stdin, 1: stdout, 2: stderr), the new file descriptor is inheritable.

Availability: not WASI.

Changed in version 3.4: The new file descriptor is now non-inheritable.

os.dup2(*fd*, *fd2*, *inheritable=True*)

Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary. Return *fd2*. The new file descriptor is inheritable by default or non-inheritable if *inheritable* is `False`.

Availability: not WASI.

Changed in version 3.4: Add the optional *inheritable* parameter.

Changed in version 3.7: Return *fd2* on success. Previously, `None` was always returned.

os.fchmod(*fd*, *mode*)

Change the mode of the file given by *fd* to the numeric *mode*. See the docs for **`chmod()`** for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(fd, mode)`.

Raises an auditing event `os.chmod` with arguments `path`, `mode`, `dir_fd`.

Availability: Unix.

The function is limited on Emscripten and WASI, see WebAssembly platforms for more information.

os.fchown(*fd*, *uid*, *gid*)

Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1. See **`chown()`**. As of Python 3.3, this is equivalent to `os.chown(fd, uid, gid)`.

Raises an auditing event `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

Availability: Unix.

The function is limited on Emscripten and WASI, see WebAssembly platforms for more information.

os.fdatasync(*fd*)

Force write of file with filedescriptor *fd* to disk. Does not force update of metadata.

Availability: Unix.

Note

This function is not available on MacOS.

os.fpathconf(*fd*, *name*, */*)

Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, **`ValueError`** is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an **`OSError`** is raised with **`errno.EINVAL`** for the error number.

As of Python 3.3, this is equivalent to `os.pathconf(fd, name)`.

Availability: Unix.

os.fstat(*fd*)

Get the status of the file descriptor *fd*. Return a **`stat_result`** object.

As of Python 3.3, this is equivalent to `os.stat(fd)`.

See also

The **`stat()`** function.

os.fstatvfs(*fd*, */*)

Return information about the filesystem containing the file associated with file descriptor *fd*, like **`statvfs()`**. As of Python 3.3, this is equivalent to `os.statvfs(fd)`.

Availability: Unix.

os.fsync(*fd*)

Force write of file with filedescriptor *fd* to disk. On Unix, this calls the native **`fsync()`** function; on Windows, the MS **`_commit()`** function.

If you're starting with a buffered Python file object *f*, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with *f* are written to disk.

Availability: Unix, Windows.

os.ftruncate(*fd*, *length*, */*)

Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size. As of Python 3.3, this is equivalent to `os.truncate(fd, length)`.

Raises an auditing event `os.truncate` with arguments `fd`, `length`.

Availability: Unix, Windows.

Changed in version 3.5: Added support for Windows

os.get_blocking(*fd*, */*)

Get the blocking mode of the file descriptor: `False` if the **`O_NONBLOCK`** flag is set, `True` if the flag is cleared.

See also **`set_blocking()`** and **`socket.socket.setblocking()`**.

Availability: Unix.

The function is limited on Emscripten and WASI, see WebAssembly platforms for more information.

New in version 3.5.

os.isatty(*fd*, */*)

Return `True` if the file descriptor *fd* is open and connected to a tty(-like) device, else `False`.

os.lockf(*fd*, *cmd*, *len*, */*)

Apply, test or remove a POSIX lock on an open file descriptor. *fd* is an open file descriptor. *cmd* specifies the command to use - one of **`F_LOCK`**, **`F_TLOCK`**, **`F_ULOCK`** or **`F_TEST`**. *len* specifies the section of the file to lock.

Raises an auditing event `os.lockf` with arguments `fd`, `cmd`, `len`.

Availability: Unix.

New in version 3.3.

os.F_LOCK
os.F_TLOCK
os.F_ULOCK
os.F_TEST

Flags that specify what action **`lockf()`** will take.

Availability: Unix.

New in version 3.3.

os.login_tty(*fd*, */*)

Prepare the tty of which fd is a file descriptor for a new login session. Make the calling process a session leader; make the tty the controlling tty, the stdin, the stdout, and the stderr of the calling process; close fd.

Availability: Unix, not Emscripten, not WASI.

New in version 3.11.

os.lseek(*fd*, *pos*, *how*, */*)

Set the current position of file descriptor *fd* to position *pos*, modified by *how*: **SEEK_SET** or `0` to set the position relative to the beginning of the file; **SEEK_CUR** or `1` to set it relative to the current position; **SEEK_END** or `2` to set it relative to the end of the file. Return the new cursor position in bytes, starting from the beginning.

os.SEEK_SET
os.SEEK_CUR
os.SEEK_END

Parameters to the **lseek()** function. Their values are 0, 1, and 2, respectively.

New in version 3.3: Some operating systems could support additional values, like **os.SEEK_HOLE** or **os.SEEK_DATA**.

os.open(*path*, *flags*, *mode=0o777*, ***, *dir_fd=None*)

Open the file *path* and set various flags according to *flags* and possibly its mode according to *mode*. When computing *mode*, the current umask value is first masked out. Return the file descriptor for the newly opened file. The new file descriptor is non-inheritable.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like **O_RDONLY** and **O_WRONLY**) are defined in the **os** module. In particular, on Windows adding **O_BINARY** is needed to open files in binary mode.

This function can support paths relative to directory descriptors with the *dir_fd* parameter.

Raises an auditing event `open` with arguments `path`, `mode`, `flags`.

Changed in version 3.4: The new file descriptor is now non-inheritable.

Note

This function is intended for low-level I/O. For normal usage, use the built-in function **open()**, which returns a file object with **read()** and **write()** methods (and many more). To wrap a file descriptor in a file object, use **fdopen()**.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an **InterruptedError** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

Changed in version 3.6: Accepts a path-like object.

The following constants are options for the *flags* parameter to the **open()** function. They can be combined using the bitwise OR operator |. Some of them are not available on all platforms. For descriptions of their availability and use, consult the *open(2)* manual page on Unix or the MSDN [https://msdn.microsoft.com/en-us/library/z0kc8e3z.aspx] on Windows.

os.O_RDONLY
os.O_WRONLY
os.O_RDWR
os.O_APPEND
os.O_CREAT
os.O_EXCL
os.O_TRUNC

The above constants are available on Unix and Windows.

os.O_DSYNC
os.O_RSYNC
os.O_SYNC

os.O_NDELAY
os.O_NONBLOCK
os.O_NOCTTY
os.O_CLOEXEC

The above constants are only available on Unix.

Changed in version 3.3: Add **O_CLOEXEC** constant.

os.O_BINARY
os.O_NOINHERIT
os.O_SHORT_LIVED
os.O_TEMPORARY
os.O_RANDOM
os.O_SEQUENTIAL
os.O_TEXT

The above constants are only available on Windows.

os.O_EVTONLY
os.O_FSYNC
os.O_SYMLINK
os.O_NOFOLLOW_ANY

The above constants are only available on macOS.

Changed in version 3.10: Add **O_EVTONLY**, **O_FSYNC**, **O_SYMLINK** and **O_NOFOLLOW_ANY** constants.

os.O_ASYNC
os.O_DIRECT
os.O_DIRECTORY
os.O_NOFOLLOW
os.O_NOATIME
os.O_PATH
os.O_TMPFILE
os.O_SHLOCK
os.O_EXLOCK

The above constants are extensions and not present if they are not defined by the C library.

Changed in version 3.4: Add **O_PATH** on systems that support

it. Add **O_TMPFILE**, only available on Linux Kernel 3.11 or newer.

os.openpty()

Open a new pseudo-terminal pair. Return a pair of file descriptors `(master, slave)` for the pty and the tty, respectively. The new file descriptors are non-inheritable. For a (slightly) more portable approach, use the **pty** module.

Availability: Unix, not Emscripten, not WASI.

Changed in version 3.4: The new file descriptors are now non-inheritable.

os.pipe()

Create a pipe. Return a pair of file descriptors `(r, w)` usable for reading and writing, respectively. The new file descriptor is non-inheritable.

Availability: Unix, Windows.

Changed in version 3.4: The new file descriptors are now non-inheritable.

os.pipe2(*flags*, */*)

Create a pipe with *flags* set atomically. *flags* can be constructed by ORing together one or more of these values: **O_NONBLOCK**, **O_CLOEXEC**. Return a pair of file descriptors `(r, w)` usable for reading and writing, respectively.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.posix_fallocate(*fd*, *offset*, *len*, */*)

Ensures that enough disk space is allocated for the file specified by *fd* starting from *offset* and continuing for *len* bytes.

Availability: Unix, not Emscripten.

New in version 3.3.

os.posix_fadvise(*fd*, *offset*, *len*, *advice*, */*)

Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations. The advice applies to the region of the file specified by *fd* starting at *offset* and continuing for *len* bytes. *advice* is one of **POSIX_FADV_NORMAL**, **POSIX_FADV_SEQUENTIAL**, **POSIX_FADV_RANDOM**, **POSIX_FADV_NOREUSE**, **POSIX_FADV_WILLNEED** or **POSIX_FADV_DONTNEED**.

Availability: Unix.

New in version 3.3.

os.POSIX_FADV_NORMAL
os.POSIX_FADV_SEQUENTIAL
os.POSIX_FADV_RANDOM
os.POSIX_FADV_NOREUSE
os.POSIX_FADV_WILLNEED
os.POSIX_FADV_DONTNEED

Flags that can be used in *advice* in **posix_fadvise()** that specify the access pattern that is likely to be used.

Availability: Unix.

New in version 3.3.

os.pread(*fd*, *n*, *offset*, */*)

Read at most *n* bytes from file descriptor *fd* at a position of *offset*, leaving the file offset unchanged.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

Availability: Unix.

New in version 3.3.

os.preadv(*fd*, *buffers*, *offset*, *flags*=*0*, */*)

Read from a file descriptor *fd* at a position of *offset* into mutable bytes-like objects *buffers*, leaving the file offset unchanged. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

The flags argument contains a bitwise OR of zero or more of the following flags:

- **RWF_HIPRI**
- **RWF_NOWAIT**

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (**sysconf()** value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of **os.readv()** and **os.pread()**.

Availability: Linux >= 2.6.30, FreeBSD >= 6.0, OpenBSD >= 2.7, AIX >= 7.1.

Using flags requires Linux >= 4.6.

New in version 3.7.

os.RWF_NOWAIT

Do not wait for data which is not immediately available. If this flag is specified, the system call will return instantly if it would have to read data from the backing storage or wait for a lock.

If some data was successfully read, it will return the number of bytes read. If no bytes were read, it will return `-1` and set errno to **errno.EAGAIN**.

Availability: Linux >= 4.14.

New in version 3.7.

os.RWF_HIPRI

High priority read/write. Allows block-based filesystems to use polling of the device, which provides lower latency, but may use additional resources.

Currently, on Linux, this feature is usable only on a file descriptor opened using the **O_DIRECT** flag.

Availability: Linux >= 4.6.

New in version 3.7.

os.pwrite(*fd*, *str*, *offset*, */*)

Write the bytestring in *str* to file descriptor *fd* at position of *offset*, leaving the file offset unchanged.

Return the number of bytes actually written.

Availability: Unix.

New in version 3.3.

os.pwritev(*fd*, *buffers*, *offset*, *flags=0*, */*)

Write the *buffers* contents to file descriptor *fd* at a offset *offset*, leaving the file offset unchanged. *buffers* must be a sequence of bytes-like objects. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

The flags argument contains a bitwise OR of zero or more of the following flags:

- **RWF_DSYNC**
- **RWF_SYNC**
- **RWF_APPEND**

Return the total number of bytes actually written.

The operating system may set a limit (**sysconf()** value 'SC_IOV_MAX') on the number of buffers that can be used.

Combine the functionality of **os.writev()** and **os.pwrite()**.

Availability: Linux >= 2.6.30, FreeBSD >= 6.0, OpenBSD >= 2.7, AIX >= 7.1.

Using flags requires Linux >= 4.6.

New in version 3.7.

os.RWF_DSYNC

Provide a per-write equivalent of the **O_DSYNC** **os.open()** flag. This flag effect applies only to the data range written by the system call.

Availability: Linux >= 4.7.

New in version 3.7.

os.RWF_SYNC

Provide a per-write equivalent of the **O_SYNC** **os.open()** flag. This flag effect applies only to the data range written by the system call.

Availability: Linux >= 4.7.

New in version 3.7.

os.RWF_APPEND

Provide a per-write equivalent of the **O_APPEND** **os.open()** flag. This flag is meaningful only for **os.pwritev()**, and its effect applies only to the data range written by the system call. The *offset* argument does not affect the write operation; the data is always appended to the end of the file. However, if the *offset* argument is -1, the current file

offset is updated.

Availability: Linux >= 4.16.

New in version 3.10.

os.read(*fd*, *n*, */*)

Read at most *n* bytes from file descriptor *fd*.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

Note

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To read a "file object" returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdin`, use its `read()` or `readline()` methods.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

os.sendfile(*out_fd*, *in_fd*, *offset*, *count*)
os.sendfile(*out_fd*, *in_fd*, *offset*, *count*, *headers=()*, *trailers=()*, *flags=0*)

Copy *count* bytes from file descriptor *in_fd* to file descriptor *out_fd* starting at *offset*. Return the number of bytes sent. When EOF is reached return `0`.

The first function notation is supported by all platforms that define `sendfile()`.

On Linux, if *offset* is given as `None`, the bytes are read from the current position of *in_fd* and the position of *in_fd* is

updated.

The second case may be used on macOS and FreeBSD where *headers* and *trailers* are arbitrary sequences of buffers that are written before and after the data from *in_fd* is written. It returns the same as the first case.

On macOS and FreeBSD, a value of `0` for *count* specifies to send until the end of *in_fd* is reached.

All platforms support sockets as *out_fd* file descriptor, and some platforms allow other types (e.g. regular file, pipe) as well.

Cross-platform applications should not use *headers*, *trailers* and *flags* arguments.

Availability: Unix, not Emscripten, not WASI.

Note

For a higher-level wrapper of **`sendfile()`**, see **`socket.socket.sendfile()`**.

New in version 3.3.

Changed in version 3.9: Parameters *out* and *in* was renamed to *out_fd* and *in_fd*.

os.set_blocking(*fd*, *blocking*, */*)

Set the blocking mode of the specified file descriptor. Set the **`O_NONBLOCK`** flag if blocking is `False`, clear the flag otherwise.

See also **`get_blocking()`** and **`socket.socket.setblocking()`**.

Availability: Unix.

The function is limited on Emscripten and WASI, see WebAssembly platforms for more information.

New in version 3.5.

os.SF_NODISKIO
os.SF_MNOWAIT
os.SF_SYNC

Parameters to the **sendfile()** function, if the implementation supports them.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.SF_NOCACHE

Parameter to the **sendfile()** function, if the implementation supports it. The data won't be cached in the virtual memory and will be freed afterwards.

Availability: Unix, not Emscripten, not WASI.

New in version 3.11.

os.splice(*src*, *dst*, *count*, *offset_src=None*, *offset_dst=None*)

Transfer *count* bytes from file descriptor *src*, starting from offset *offset_src*, to file descriptor *dst*, starting from offset *offset_dst*. At least one of the file descriptors must refer to a pipe. If *offset_src* is None, then *src* is read from the current position; respectively for *offset_dst*. The offset associated to the file descriptor that refers to a pipe must be `None`. The files pointed by *src* and *dst* must reside in the same filesystem, otherwise an **OSError** is raised with **errno** set to **errno.EXDEV**.

This copy is done without the additional cost of transferring data from the kernel to user space and then back into the kernel. Additionally, some filesystems could implement extra optimizations. The copy is done as if both files are opened as binary.

Upon successful completion, returns the number of bytes

spliced to or from the pipe. A return value of 0 means end of input. If *src* refers to a pipe, then this means that there was no data to transfer, and it would not make sense to block because there are no writers connected to the write end of the pipe.

Availability: Linux >= 2.6.17 with glibc >= 2.5

New in version 3.10.

os.SPLICE_F_MOVE
os.SPLICE_F_NONBLOCK
os.SPLICE_F_MORE

New in version 3.10.

os.readv(*fd*, *buffers*, */*)

Read from a file descriptor *fd* into a number of mutable bytes-like objects *buffers*. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (**`sysconf()`** value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Availability: Unix.

New in version 3.3.

os.tcgetpgrp(*fd*, */*)

Return the process group associated with the terminal given by *fd* (an open file descriptor as returned by **`os.open()`**).

Availability: Unix, not WASI.

os.tcsetpgrp(*fd*, *pg*, */*)

Set the process group associated with the terminal given by *fd*

(an open file descriptor as returned by `os.open()`) to *pg*.

Availability: Unix, not WASI.

os.ttyname(*fd*, */*)

Return a string which specifies the terminal device associated with file descriptor *fd*. If *fd* is not associated with a terminal device, an exception is raised.

Availability: Unix.

os.write(*fd*, *str*, */*)

Write the bytestring in *str* to file descriptor *fd*.

Return the number of bytes actually written.

Note

This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To write a "file object" returned by the built-in function `open()` or by `popen()` or `fdopen()`, or `sys.stdout` or `sys.stderr`, use its `write()` method.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an `InterruptedError` exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

os.writev(*fd*, *buffers*, */*)

Write the contents of *buffers* to file descriptor *fd*. *buffers* must be a sequence of bytes-like objects. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

Returns the total number of bytes actually written.

The operating system may set a limit (`sysconf()` value

'SC_IOV_MAX') on the number of buffers that can be used.

Availability: Unix.

New in version 3.3.

Querying the size of a terminal

New in version 3.3.

os.get_terminal_size(*fd=STDOUT_FILENO*, */*)

Return the size of the terminal window as `(columns, lines)`, tuple of type **`terminal_size`**.

The optional argument `fd` (default `STDOUT_FILENO`, or standard output) specifies which file descriptor should be queried.

If the file descriptor is not connected to a terminal, an **`OSError`** is raised.

`shutil.get_terminal_size()` is the high-level function which should normally be used, `os.get_terminal_size` is the low-level implementation.

Availability: Unix, Windows.

class os.terminal_size

A subclass of tuple, holding `(columns, lines)` of the terminal window size.

columns

Width of the terminal window in characters.

lines

Height of the terminal window in characters.

Inheritance of File Descriptors

New in version 3.4.

A file descriptor has an “inheritable” flag which indicates if the file descriptor can be inherited by child processes. Since Python 3.4, file descriptors created by Python are non-inheritable by default.

On UNIX, non-inheritable file descriptors are closed in child processes at the execution of a new program, other file descriptors are inherited.

On Windows, non-inheritable handles and file descriptors are closed in child processes, except for standard streams (file descriptors 0, 1 and 2: stdin, stdout and stderr), which are always inherited. Using **`spawn*`** functions, all inheritable handles and all inheritable file descriptors are inherited. Using the **`subprocess`** module, all file descriptors except standard streams are closed, and inheritable handles are only inherited if the *close_fds* parameter is `False`.

On WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`, the file descriptor cannot be modified.

os.get_inheritable(*fd*, */*)

Get the “inheritable” flag of the specified file descriptor (a boolean).

os.set_inheritable(*fd*, *inheritable*, */*)

Set the “inheritable” flag of the specified file descriptor.

os.get_handle_inheritable(*handle*, */*)

Get the “inheritable” flag of the specified handle (a boolean).

Availability: Windows.

os.set_handle_inheritable(*handle*, *inheritable*, */*)

Set the “inheritable” flag of the specified handle.

Availability: Windows.

Files and Directories

On some Unix platforms, many of these functions support one or more of these features:

- **specifying a file descriptor:** Normally the *path* argument provided to functions in the **`os`** module must be a string specifying a file path. However, some functions now alternatively accept an open file descriptor for their *path* argument. The function will then operate on the file referred to by the descriptor. (For POSIX systems, Python will call the variant of the function prefixed with `f` (e.g. call `fchdir` instead of `chdir`).)

  You can check whether or not *path* can be specified as a file descriptor for a particular function on your platform using **`os.supports_fd`**. If this functionality is unavailable, using it will raise a **`NotImplementedError`**.

  If the function also supports *dir_fd* or *follow_symlinks* arguments, it's an error to specify one of those when supplying *path* as a file descriptor.

- **paths relative to directory descriptors:** If *dir_fd* is not `None`, it should be a file descriptor referring to a directory, and the path to operate on should be relative; path will then be relative to that directory. If the path is absolute, *dir_fd* is ignored. (For POSIX systems, Python will call the variant of the function with an `at` suffix and possibly prefixed with `f` (e.g. call `faccessat` instead of `access`).

  You can check whether or not *dir_fd* is supported for a particular function on your platform using **`os.supports_dir_fd`**. If it's unavailable, using it will raise a **`NotImplementedError`**.

- **not following symlinks:** If *follow_symlinks* is `False`, and the last element of the path to operate on is a symbolic link, the function will operate on the symbolic link itself rather than the file pointed to by the link. (For POSIX systems, Python

will call the `l...` variant of the function.)

You can check whether or not *follow_symlinks* is supported for a particular function on your platform using **`os.supports_follow_symlinks`**. If it's unavailable, using it will raise a **`NotImplementedError`**.

os.access(*path*, *mode*, ***, *dir_fd=None*, *effective_ids=False*, *follow_symlinks=True*)

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a suid/sgid environment to test if the invoking user has the specified access to *path*. *mode* should be **`F_OK`** to test the existence of *path*, or it can be the inclusive OR of one or more of **`R_OK`**, **`W_OK`**, and **`X_OK`** to test permissions. Return **`True`** if access is allowed, **`False`** if not. See the Unix man page *access(2)* for more information.

This function can support specifying paths relative to directory descriptors and not following symlinks.

If *effective_ids* is `True`, **`access()`** will perform its access checks using the effective uid/gid instead of the real uid/gid. *effective_ids* may not be supported on your platform; you can check whether or not it is available using **`os.supports_effective_ids`**. If it is unavailable, using it will raise a **`NotImplementedError`**.

Note

Using **`access()`** to check if a user is authorized to e.g. open a file before actually doing so using **`open()`** creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use EAFP techniques. For example:

```
if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
```

```
return "some default data"
```

is better written as:

```
try:
    fp = open("myfile")
except PermissionError:
    return "some default data"
else:
    with fp:
        return fp.read()
```

Note

I/O operations may fail even when **access()** indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

Changed in version 3.3: Added the *dir_fd*, *effective_ids*, and *follow_symlinks* parameters.

Changed in version 3.6: Accepts a path-like object.

os.F_OK
os.R_OK
os.W_OK
os.X_OK

Values to pass as the *mode* parameter of **access()** to test the existence, readability, writability and executability of *path*, respectively.

os.chdir(*path*)

Change the current working directory to *path*.

This function can support specifying a file descriptor. The descriptor must refer to an opened directory, not an open file.

This function can raise **OSError** and subclasses such as

FileNotFoundError, **PermissionError**, and **NotADirectoryError**.

Raises an auditing event `os.chdir` with argument `path`.

New in version 3.3: Added support for specifying *path* as a file descriptor on some platforms.

Changed in version 3.6: Accepts a path-like object.

os.chflags(*path*, *flags*, ***, *follow_symlinks=True*)

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the **stat** module):

- **stat.UF_NODUMP**
- **stat.UF_IMMUTABLE**
- **stat.UF_APPEND**
- **stat.UF_OPAQUE**
- **stat.UF_NOUNLINK**
- **stat.UF_COMPRESSED**
- **stat.UF_HIDDEN**
- **stat.SF_ARCHIVED**
- **stat.SF_IMMUTABLE**
- **stat.SF_APPEND**
- **stat.SF_NOUNLINK**
- **stat.SF_SNAPSHOT**

This function can support not following symlinks.

Raises an auditing event `os.chflags` with arguments `path`, `flags`.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3: The *follow_symlinks* argument.

Changed in version 3.6: Accepts a path-like object.

os.chmod(*path*, *mode*, ***, *dir_fd=None*, *follow_symlinks=True*)

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the **stat** module) or bitwise ORed combinations of them:

- **stat.S_ISUID**
- **stat.S_ISGID**
- **stat.S_ENFMT**
- **stat.S_ISVTX**
- **stat.S_IREAD**
- **stat.S_IWRITE**
- **stat.S_IEXEC**
- **stat.S_IRWXU**
- **stat.S_IRUSR**
- **stat.S_IWUSR**
- **stat.S_IXUSR**
- **stat.S_IRWXG**
- **stat.S_IRGRP**
- **stat.S_IWGRP**
- **stat.S_IXGRP**
- **stat.S_IRWXO**
- **stat.S_IROTH**
- **stat.S_IWOTH**
- **stat.S_IXOTH**

This function can support specifying a file descriptor, paths relative to directory descriptors and not following symlinks.

Note

Although Windows supports **chmod()**, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

The function is limited on Emscripten and WASI, see WebAssembly platforms for more information.

Raises an auditing event `os.chmod` with arguments `path`, `mode`, `dir_fd`.

New in version 3.3: Added support for specifying *path* as an

open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

Changed in version 3.6: Accepts a path-like object.

os.chown(*path*, *uid*, *gid*, ***, *dir_fd=None*, *follow_symlinks=True*)

Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

This function can support specifying a file descriptor, paths relative to directory descriptors and not following symlinks.

See **`shutil.chown()`** for a higher-level function that accepts names in addition to numeric ids.

Raises an auditing event `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

Availability: Unix.

The function is limited on Emscripten and WASI, see WebAssembly platforms for more information.

New in version 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

Changed in version 3.6: Supports a path-like object.

os.chroot(*path*)

Change the root directory of the current process to *path*.

Availability: Unix, not Emscripten, not WASI.

Changed in version 3.6: Accepts a path-like object.

os.fchdir(*fd*)

Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must

refer to an opened directory, not an open file. As of Python 3.3, this is equivalent to `os.chdir(fd)`.

Raises an auditing event `os.chdir` with argument `path`.

Availability: Unix.

os.getcwd()

Return a string representing the current working directory.

os.getcwdb()

Return a bytestring representing the current working directory.

Changed in version 3.8: The function now uses the UTF-8 encoding on Windows, rather than the ANSI code page: see **PEP 529** [https://peps.python.org/pep-0529/] for the rationale. The function is no longer deprecated on Windows.

os.lchflags(*path*, *flags*)

Set the flags of *path* to the numeric *flags*, like **`chflags()`**, but do not follow symbolic links. As of Python 3.3, this is equivalent to `os.chflags(path, flags, follow_symlinks=False)`.

Raises an auditing event `os.chflags` with arguments `path`, `flags`.

Availability: Unix, not Emscripten, not WASI.

Changed in version 3.6: Accepts a path-like object.

os.lchmod(*path*, *mode*)

Change the mode of *path* to the numeric *mode*. If path is a symlink, this affects the symlink rather than the target. See the docs for **`chmod()`** for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(path, mode, follow_symlinks=False)`.

Raises an auditing event `os.chmod` with arguments `path`, `mode`, `dir_fd`.

Availability: Unix.

Changed in version 3.6: Accepts a path-like object.

os.lchown(*path*, *uid*, *gid*)

Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links. As of Python 3.3, this is equivalent to `os.chown(path, uid, gid, follow_symlinks=False)`.

Raises an auditing event `os.chown` with arguments `path`, `uid`, `gid`, `dir_fd`.

Availability: Unix.

Changed in version 3.6: Accepts a path-like object.

os.link(*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*, *follow_symlinks=True*)

Create a hard link pointing to *src* named *dst*.

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply paths relative to directory descriptors, and not following symlinks.

Raises an auditing event `os.link` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Availability: Unix, Windows.

Changed in version 3.2: Added Windows support.

New in version 3.3: Added the *src_dir_fd*, *dst_dir_fd*, and *follow_symlinks* arguments.

Changed in version 3.6: Accepts a path-like object for *src* and *dst*.

os.listdir(*path='.'*)

Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order, and does not include the special entries `'.'` and `'..'` even if they are present in the directory. If a file is removed from or added to the directory during the call of this function, whether a name for that file be included is unspecified.

path may be a path-like object. If *path* is of type `bytes` (directly or indirectly through the **`PathLike`** interface), the filenames returned will also be of type `bytes`; in all other circumstances, they will be of type `str`.

This function can also support specifying a file descriptor; the file descriptor must refer to a directory.

Raises an auditing event `os.listdir` with argument `path`.

Note

To encode `str` filenames to `bytes`, use **`fsencode()`**.

See also

The **`scandir()`** function returns directory entries along with file attribute information, giving better performance for many common use cases.

Changed in version 3.2: The *path* parameter became optional.

New in version 3.3: Added support for specifying *path* as an open file descriptor.

Changed in version 3.6: Accepts a path-like object.

os.lstat(*path*, ***, *dir_fd=None*)

Perform the equivalent of an **`lstat()`** system call on the given path. Similar to **`stat()`**, but does not follow symbolic links. Return a **`stat_result`** object.

On platforms that do not support symbolic links, this is an alias for **`stat()`**.

As of Python 3.3, this is equivalent to `os.stat(path, dir_fd=dir_fd, follow_symlinks=False)`.

This function can also support paths relative to directory descriptors.

See also

The **`stat()`** function.

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a path-like object.

Changed in version 3.8: On Windows, now opens reparse points that represent another path (name surrogates), including symbolic links and directory junctions. Other kinds of reparse points are resolved by the operating system as for **`stat()`**.

os.mkdir(*path*, *mode=0o777*, ***, *dir_fd=None*)

Create a directory named *path* with numeric mode *mode*.

If the directory already exists, **`FileExistsError`** is raised. If a parent directory in the path does not exist, **`FileNotFoundError`** is raised.

On some systems, *mode* is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the *mode*) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call **`chmod()`** explicitly to set them.

This function can also support paths relative to directory

descriptors.

It is also possible to create temporary directories; see the **tempfile** module's **tempfile.mkdtemp()** function.

Raises an auditing event `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a path-like object.

os.makedirs(*name*, *mode=0o777*, *exist_ok=False*)

Recursive directory creation function. Like **mkdir()**, but makes all intermediate-level directories needed to contain the leaf directory.

The *mode* parameter is passed to **mkdir()** for creating the leaf directory; see the mkdir() description for how it is interpreted. To set the file permission bits of any newly created parent directories you can set the umask before invoking **makedirs()**. The file permission bits of existing parent directories are not changed.

If *exist_ok* is `False` (the default), a **FileExistsError** is raised if the target directory already exists.

Note

makedirs() will become confused if the path elements to create include **pardir** (eg. ".." on UNIX systems).

This function handles UNC paths correctly.

Raises an auditing event `os.mkdir` with arguments `path`, `mode`, `dir_fd`.

New in version 3.2: The *exist_ok* parameter.

Changed in version 3.4.1: Before Python 3.4.1, if *exist_ok* was `True` and the directory existed, **makedirs()** would still

raise an error if *mode* did not match the mode of the existing directory. Since this behavior was impossible to implement safely, it was removed in Python 3.4.1. See bpo-21082 [https://bugs.python.org/issue?@action=redirect&bpo=21082].

Changed in version 3.6: Accepts a path-like object.

Changed in version 3.7: The *mode* argument no longer affects the file permission bits of newly created intermediate-level directories.

os.mkfifo(*path*, *mode=0o666*, ***, *dir_fd=None*)

Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The current umask value is first masked out from the mode.

This function can also support paths relative to directory descriptors.

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with **`os.unlink()`**). Generally, FIFOs are used as rendezvous between "client" and "server" type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that **`mkfifo()`** doesn't open the FIFO — it just creates the rendezvous point.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a path-like object.

os.mknod(*path*, *mode=0o600*, *device=0*, ***, *dir_fd=None*)

Create a filesystem node (file, device special file or named pipe) named *path*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in **`stat`**). For `stat.S_IFCHR` and

`stat.S_IFBLK`, *device* defines the newly created device special file (probably using **`os.makedev()`**), otherwise it is ignored.

This function can also support paths relative to directory descriptors.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a path-like object.

os.major(*device*, */*)

Extract the device major number from a raw device number (usually the **`st_dev`** or **`st_rdev`** field from **`stat`**).

os.minor(*device*, */*)

Extract the device minor number from a raw device number (usually the **`st_dev`** or **`st_rdev`** field from **`stat`**).

os.makedev(*major*, *minor*, */*)

Compose a raw device number from the major and minor device numbers.

os.pathconf(*path*, *name*)

Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, **`ValueError`** is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an

OSError is raised with **errno.EINVAL** for the error number.

This function can support specifying a file descriptor.

Availability: Unix.

Changed in version 3.6: Accepts a path-like object.

os.pathconf_names

Dictionary mapping names accepted by **pathconf()** and **fpathconf()** to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

os.readlink(*path*, *, *dir_fd=None*)

Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using `os.path.join(os.path.dirname(path), result)`.

If the *path* is a string object (directly or indirectly through a **PathLike** interface), the result will also be a string object, and the call may raise a UnicodeDecodeError. If the *path* is a bytes object (direct or indirectly), the result will be a bytes object.

This function can also support paths relative to directory descriptors.

When trying to resolve a path that may contain links, use **realpath()** to properly handle recursion and platform differences.

Availability: Unix, Windows.

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a path-like object on Unix.

Changed in version 3.8: Accepts a path-like object and a bytes object on Windows.

Changed in version 3.8: Added support for directory junctions, and changed to return the substitution path (which typically includes `\\?\` prefix) rather than the optional "print name" field that was previously returned.

os.remove(*path*, *, *dir_fd=None*)

Remove (delete) the file *path*. If *path* is a directory, an **`OSError`** is raised. Use **`rmdir()`** to remove directories. If the file does not exist, a **`FileNotFoundError`** is raised.

This function can support paths relative to directory descriptors.

On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

This function is semantically identical to **`unlink()`**.

Raises an auditing event `os.remove` with arguments `path`, `dir_fd`.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a path-like object.

os.removedirs(*name*)

Remove directories recursively. Works like **`rmdir()`** except that, if the leaf directory is successfully removed, **`removedirs()`** tries to successively remove every parent directory mentioned in *path* until an error is raised (which is ignored, because it generally means that a parent directory is

not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory `'foo/bar/baz'`, and then remove `'foo/bar'` and `'foo'` if they are empty. Raises **`OSError`** if the leaf directory could not be successfully removed.

Raises an auditing event `os.remove` with arguments `path`, `dir_fd`.

Changed in version 3.6: Accepts a path-like object.

os.rename(*src*, *dst*, *, *src_dir_fd=None*, *dst_dir_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* exists, the operation will fail with an **`OSError`** subclass in a number of cases:

On Windows, if *dst* exists a **`FileExistsError`** is always raised.

On Unix, if *src* is a file and *dst* is a directory or vice-versa, an **`IsADirectoryError`** or a **`NotADirectoryError`** will be raised respectively. If both are directories and *dst* is empty, *dst* will be silently replaced. If *dst* is a non-empty directory, an **`OSError`** is raised. If both are files, *dst* will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply paths relative to directory descriptors.

If you want cross-platform overwriting of the destination, use **`replace()`**.

Raises an auditing event `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

New in version 3.3: The *src_dir_fd* and *dst_dir_fd* arguments.

Changed in version 3.6: Accepts a path-like object for *src* and

dst.

os.renames(*old*, *new*)

Recursive directory or file renaming function. Works like **`rename()`**, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using **`removedirs()`**.

Note

This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

Raises an auditing event `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

Changed in version 3.6: Accepts a path-like object for *old* and *new*.

os.replace(*src*, *dst*, ***, *src_dir_fd=None*, *dst_dir_fd=None*)

Rename the file or directory *src* to *dst*. If *dst* is a non-empty directory, **`OSError`** will be raised. If *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply paths relative to directory descriptors.

Raises an auditing event `os.rename` with arguments `src`, `dst`, `src_dir_fd`, `dst_dir_fd`.

New in version 3.3.

Changed in version 3.6: Accepts a path-like object for *src* and *dst*.

os.rmdir(*path*, *, *dir_fd=None*)

Remove (delete) the directory *path*. If the directory does not exist or is not empty, a **FileNotFoundError** or an **OSError** is raised respectively. In order to remove whole directory trees, **shutil.rmtree()** can be used.

This function can support paths relative to directory descriptors.

Raises an auditing event `os.rmdir` with arguments `path`, `dir_fd`.

New in version 3.3: The *dir_fd* parameter.

Changed in version 3.6: Accepts a path-like object.

os.scandir(*path='.'*)

Return an iterator of **os.DirEntry** objects corresponding to the entries in the directory given by *path*. The entries are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included. If a file is removed from or added to the directory after creating the iterator, whether an entry for that file be included is unspecified.

Using **scandir()** instead of **listdir()** can significantly increase the performance of code that also needs file type or file attribute information, because **os.DirEntry** objects expose this information if the operating system provides it when scanning a directory. All **os.DirEntry** methods may perform a system call, but **is_dir()** and **is_file()** usually only require a system call for symbolic links; **os.DirEntry.stat()** always requires a system call on Unix but only requires one for symbolic links on Windows.

path may be a path-like object. If *path* is of type `bytes` (directly or indirectly through the **PathLike** interface), the type of the **name** and **path** attributes of each **os.DirEntry** will be `bytes`; in all other circumstances, they will be of type `str`.

This function can also support specifying a file descriptor; the file descriptor must refer to a directory.

Raises an auditing event `os.scandir` with argument `path`.

The **`scandir()`** iterator supports the context manager protocol and has the following method:

scandir.close()

Close the iterator and free acquired resources.

This is called automatically when the iterator is exhausted or garbage collected, or when an error happens during iterating. However it is advisable to call it explicitly or use the **`with`** statement.

New in version 3.6.

The following example shows a simple use of **`scandir()`** to display all the files (excluding directories) in the given *path* that don't start with `'.'`. The `entry.is_file()` call will generally not make an additional system call:

```
with os.scandir(path) as it:
    for entry in it:
        if not entry.name.startswith('.') and entry
            print(entry.name)
```

Note

On Unix-based systems, **`scandir()`** uses the system's opendir() [https://pubs.opengroup.org/onlinepubs/009695399/functions/opendir.html] and readdir() [https://pubs.opengroup.org/onlinepubs/009695399/functions/readdir_r.html] functions. On Windows, it uses the Win32 FindFirstFileW [https://msdn.microsoft.com/en-us/library/windows/desktop/aa364418(v=vs.85).aspx] and FindNextFileW [https://msdn.microsoft.com/en-us/library/windows/desktop/aa364428(v=vs.85).aspx] functions.

New in version 3.5.

New in version 3.6: Added support for the context manager protocol and the **close()** method. If a **scandir()** iterator is neither exhausted nor explicitly closed a **ResourceWarning** will be emitted in its destructor.

The function accepts a path-like object.

Changed in version 3.7: Added support for file descriptors on Unix.

class os.DirEntry

Object yielded by **scandir()** to expose the file path and other file attributes of a directory entry.

scandir() will provide as much of this information as possible without making additional system calls. When a `stat()` or `lstat()` system call is made, the `os.DirEntry` object will cache the result.

`os.DirEntry` instances are not intended to be stored in long-lived data structures; if you know the file metadata has changed or if a long time has elapsed since calling **scandir()**, call `os.stat(entry.path)` to fetch up-to-date information.

Because the `os.DirEntry` methods can make operating system calls, they may also raise **OSError**. If you need very fine-grained control over errors, you can catch **OSError** when calling one of the `os.DirEntry` methods and handle as appropriate.

To be directly usable as a path-like object, `os.DirEntry` implements the **PathLike** interface.

Attributes and methods on a `os.DirEntry` instance are as follows:

name

The entry's base filename, relative to the **scandir()** *path* argument.

The **name** attribute will be `bytes` if the **scandir()** *path* argument is of type `bytes` and `str` otherwise. Use **fsdecode()** to decode byte filenames.

path

The entry's full path name: equivalent to `os.path.join(scandir_path, entry.name)` where *scandir_path* is the **scandir()** *path* argument. The path is only absolute if the **scandir()** *path* argument was absolute. If the **scandir()** *path* argument was a file descriptor, the **path** attribute is the same as the **name** attribute.

The **path** attribute will be `bytes` if the **scandir()** *path* argument is of type `bytes` and `str` otherwise. Use **fsdecode()** to decode byte filenames.

inode()

Return the inode number of the entry.

The result is cached on the `os.DirEntry` object. Use `os.stat(entry.path, follow_symlinks=False).st_ino` to fetch up-to-date information.

On the first, uncached call, a system call is required on Windows but not on Unix.

is_dir(*, *follow_symlinks* = *True*)

Return `True` if this entry is a directory or a symbolic link pointing to a directory; return `False` if the entry is or points to any other kind of file, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a directory (without following symlinks); return `False` if the entry is any other kind of file or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call **`os.stat()`** along with **`stat.S_ISDIR()`** to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, for non-symlinks, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`. If the entry is a symlink, a system call will be required to follow the symlink unless *follow_symlinks* is `False`.

This method can raise **`OSError`**, such as **`PermissionError`**, but **`FileNotFoundError`** is caught and not raised.

is_file(*, *follow_symlinks* = *True*)

Return `True` if this entry is a file or a symbolic link pointing to a file; return `False` if the entry is or points to a directory or other non-file entry, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a file (without following symlinks); return `False` if the entry is a directory or other non-file entry, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Caching, system calls made, and exceptions raised are as per **`is_dir()`**.

is_symlink()

Return `True` if this entry is a symbolic link (even if broken); return `False` if the entry points to a directory or any kind of file, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call **`os.path.islink()`** to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`.

This method can raise **`OSError`**, such as **`PermissionError`**, but **`FileNotFoundError`** is caught and not raised.

stat(*, *follow_symlinks=True*)

Return a **`stat_result`** object for this entry. This method follows symbolic links by default; to stat a symbolic link add the `follow_symlinks=False` argument.

On Unix, this method always requires a system call. On Windows, it only requires a system call if *follow_symlinks* is `True` and the entry is a reparse point (for example, a symbolic link or directory junction).

On Windows, the `st_ino`, `st_dev` and `st_nlink` attributes of the **`stat_result`** are always set to zero. Call **`os.stat()`** to get these attributes.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call **`os.stat()`** to fetch up-to-date information.

Note that there is a nice correspondence between several attributes and methods of `os.DirEntry` and of **`pathlib.Path`**. In particular, the `name` attribute has the same meaning, as do the `is_dir()`, `is_file()`, `is_symlink()` and `stat()` methods.

New in version 3.5.

Changed in version 3.6: Added support for the **`PathLike`** interface. Added support for **`bytes`** paths on Windows.

os.stat(*path*, *, *dir_fd* = *None*, *follow_symlinks* = *True*)

Get the status of a file or a file descriptor. Perform the equivalent of a **`stat()`** system call on the given path. *path* may be specified as either a string or bytes – directly or indirectly through the **`PathLike`** interface – or as an open file descriptor. Return a **`stat_result`** object.

This function normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use **`lstat()`**.

This function can support specifying a file descriptor and not following symlinks.

On Windows, passing `follow_symlinks=False` will disable following all name-surrogate reparse points, which includes symlinks and directory junctions. Other types of reparse points that do not resemble links or that the operating system is unable to follow will be opened directly. When following a chain of multiple links, this may result in the original link being returned instead of the non-link that prevented full traversal. To obtain stat results for the final path in this case, use the **`os.path.realpath()`** function to resolve the path name as far as possible and call **`lstat()`** on the result. This does not apply to dangling symlinks or junction points, which will raise the usual exceptions.

Example:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
os.stat_result(st_mode=33188, st_ino=7876932, st_de
st_nlink=1, st_uid=501, st_gid=501, st_size=264, st
st_mtime=1297230027, st_ctime=1297230027)
>>> statinfo.st_size
264
```

See also

`fstat()` and **`lstat()`** functions.

New in version 3.3: Added the *dir_fd* and *follow_symlinks* arguments, specifying a file descriptor instead of a path.

Changed in version 3.6: Accepts a path-like object.

Changed in version 3.8: On Windows, all reparse points that can be resolved by the operating system are now followed, and passing `follow_symlinks=False` disables following all name surrogate reparse points. If the operating system reaches a reparse point that it is not able to follow, *stat* now returns the information for the original path as if `follow_symlinks=False` had been specified instead of raising an error.

class os.stat_result

Object whose attributes correspond roughly to the members of the **`stat`** structure. It is used for the result of **`os.stat()`**, **`os.fstat()`** and **`os.lstat()`**.

Attributes:

st_mode

File mode: file type and file mode bits (permissions).

st_ino

Platform dependent, but if non-zero, uniquely identifies the file for a given value of `st_dev`. Typically:

- the inode number on Unix,
- the file index [https://msdn.microsoft.com/en-us/library/aa363788] on Windows

st_dev

Identifier of the device on which this file resides.

st_nlink

Number of hard links.

st_uid

User identifier of the file owner.

st_gid
: Group identifier of the file owner.

st_size
: Size of the file in bytes, if it is a regular file or a symbolic link. The size of a symbolic link is the length of the pathname it contains, without a terminating null byte.

Timestamps:

st_atime
: Time of most recent access expressed in seconds.

st_mtime
: Time of most recent content modification expressed in seconds.

st_ctime
: Platform dependent:

  - the time of most recent metadata change on Unix,
  - the time of creation on Windows, expressed in seconds.

st_atime_ns
: Time of most recent access expressed in nanoseconds as an integer.

st_mtime_ns
: Time of most recent content modification expressed in nanoseconds as an integer.

st_ctime_ns

Platform dependent:

- the time of most recent metadata change on Unix,
- the time of creation on Windows, expressed in nanoseconds as an integer.

Note

The exact meaning and resolution of the **st_atime**, **st_mtime**, and **st_ctime** attributes depend on the operating system and the file system. For example, on Windows systems using the FAT or FAT32 file systems, **st_mtime** has 2-second resolution, and **st_atime** has only 1-day resolution. See your operating system documentation for details.

Similarly, although **st_atime_ns**, **st_mtime_ns**, and **st_ctime_ns** are always expressed in nanoseconds, many systems do not provide nanosecond precision. On systems that do provide nanosecond precision, the floating-point object used to store **st_atime**, **st_mtime**, and **st_ctime** cannot preserve all of it, and as such will be slightly inexact. If you need the exact timestamps you should always use **st_atime_ns**, **st_mtime_ns**, and **st_ctime_ns**.

On some Unix systems (such as Linux), the following attributes may also be available:

st_blocks

Number of 512-byte blocks allocated for file. This may be smaller than **st_size**/512 when the file has holes.

st_blksize

“Preferred” blocksize for efficient file system I/O. Writing to a file in smaller chunks may cause an inefficient read-modify-rewrite.

st_rdev
: Type of device if an inode device.

st_flags
: User defined flags for file.

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

st_gen
: File generation number.

st_birthtime
: Time of file creation.

On Solaris and derivatives, the following attributes may also be available:

st_fstype
: String that uniquely identifies the type of the filesystem that contains the file.

On macOS systems, the following attributes may also be available:

st_rsize
: Real size of the file.

st_creator
: Creator of the file.

st_type
: File type.

On Windows systems, the following attributes are also available:

st_file_attributes

Windows file attributes: `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by **`GetFileInformationByHandle()`**. See the `FILE_ATTRIBUTE_*` constants in the **`stat`** module.

st_reparse_tag

When **`st_file_attributes`** has the `FILE_ATTRIBUTE_REPARSE_POINT` set, this field contains the tag identifying the type of reparse point. See the `IO_REPARSE_TAG_*` constants in the **`stat`** module.

The standard module **`stat`** defines functions and constants that are useful for extracting information from a **`stat`** structure. (On Windows, some items are filled with dummy values.)

For backward compatibility, a **`stat_result`** instance is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the **`stat`** structure, in the order **`st_mode`**, **`st_ino`**, **`st_dev`**, **`st_nlink`**, **`st_uid`**, **`st_gid`**, **`st_size`**, **`st_atime`**, **`st_mtime`**, **`st_ctime`**. More items may be added at the end by some implementations. For compatibility with older Python versions, accessing **`stat_result`** as a tuple always returns integers.

New in version 3.3: Added the **`st_atime_ns`**, **`st_mtime_ns`**, and **`st_ctime_ns`** members.

New in version 3.5: Added the **`st_file_attributes`** member on Windows.

Changed in version 3.5: Windows now returns the file index as **`st_ino`** when available.

New in version 3.7: Added the **`st_fstype`** member to Solaris/derivatives.

New in version 3.8: Added the **st_reparse_tag** member on Windows.

Changed in version 3.8: On Windows, the **st_mode** member now identifies special files as **S_IFCHR**, **S_IFIFO** or **S_IFBLK** as appropriate.

os.statvfs(*path*)

Perform a **statvfs()** system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the **statvfs** structure, namely: **f_bsize**, **f_frsize**, **f_blocks**, **f_bfree**, **f_bavail**, **f_files**, **f_ffree**, **f_favail**, **f_flag**, **f_namemax**, **f_fsid**.

Two module-level constants are defined for the **f_flag** attribute's bit-flags: if **ST_RDONLY** is set, the filesystem is mounted read-only, and if **ST_NOSUID** is set, the semantics of setuid/setgid bits are disabled or not supported.

Additional module-level constants are defined for GNU/glibc based systems. These are **ST_NODEV** (disallow access to device special files), **ST_NOEXEC** (disallow program execution), **ST_SYNCHRONOUS** (writes are synced at once), **ST_MANDLOCK** (allow mandatory locks on an FS), **ST_WRITE** (write on file/directory/symlink), **ST_APPEND** (append-only file), **ST_IMMUTABLE** (immutable file), **ST_NOATIME** (do not update access times), **ST_NODIRATIME** (do not update directory access times), **ST_RELATIME** (update atime relative to mtime/ctime).

This function can support specifying a file descriptor.

Availability: Unix.

Changed in version 3.2: The **ST_RDONLY** and **ST_NOSUID** constants were added.

New in version 3.3: Added support for specifying *path* as an open file descriptor.

Changed in version 3.4: The **ST_NODEV**, **ST_NOEXEC**, **ST_SYNCHRONOUS**, **ST_MANDLOCK**, **ST_WRITE**, **ST_APPEND**, **ST_IMMUTABLE**, **ST_NOATIME**, **ST_NODIRATIME**, and **ST_RELATIME** constants were added.

Changed in version 3.6: Accepts a path-like object.

New in version 3.7: Added **f_fsid**.

os.supports_dir_fd

A **set** object indicating which functions in the **os** module accept an open file descriptor for their *dir_fd* parameter. Different platforms provide different features, and the underlying functionality Python uses to implement the *dir_fd* parameter is not available on all platforms Python supports. For consistency's sake, functions that may support *dir_fd* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `None` for *dir_fd* is always supported on all platforms.)

To check whether a particular function accepts an open file descriptor for its *dir_fd* parameter, use the `in` operator on `supports_dir_fd`. As an example, this expression evaluates to `True` if **os.stat()** accepts open file descriptors for *dir_fd* on the local platform:

```
os.stat in os.supports_dir_fd
```

Currently *dir_fd* parameters only work on Unix platforms; none of them work on Windows.

New in version 3.3.

os.supports_effective_ids

A **set** object indicating whether **os.access()** permits specifying `True` for its *effective_ids* parameter on the local platform. (Specifying `False` for *effective_ids* is always supported on all platforms.) If the local platform supports it, the collection will contain **os.access()**; otherwise it will

be empty.

This expression evaluates to `True` if **`os.access()`** supports `effective_ids=True` on the local platform:

```
os.access in os.supports_effective_ids
```

Currently *effective_ids* is only supported on Unix platforms; it does not work on Windows.

New in version 3.3.

os.supports_fd

A **`set`** object indicating which functions in the **`os`** module permit specifying their *path* parameter as an open file descriptor on the local platform. Different platforms provide different features, and the underlying functionality Python uses to accept open file descriptors as *path* arguments is not available on all platforms Python supports.

To determine whether a particular function permits specifying an open file descriptor for its *path* parameter, use the `in` operator on `supports_fd`. As an example, this expression evaluates to `True` if **`os.chdir()`** accepts open file descriptors for *path* on your local platform:

```
os.chdir in os.supports_fd
```

New in version 3.3.

os.supports_follow_symlinks

A **`set`** object indicating which functions in the **`os`** module accept `False` for their *follow_symlinks* parameter on the local platform. Different platforms provide different features, and the underlying functionality Python uses to implement *follow_symlinks* is not available on all platforms Python supports. For consistency's sake, functions that may support *follow_symlinks* always allow specifying the parameter, but will throw an exception if the functionality is used when it's not locally available. (Specifying `True` for *follow_symlinks* is

always supported on all platforms.)

To check whether a particular function accepts `False` for its *follow_symlinks* parameter, use the `in` operator on `supports_follow_symlinks`. As an example, this expression evaluates to `True` if you may specify `follow_symlinks=False` when calling **`os.stat()`** on the local platform:

```
os.stat in os.supports_follow_symlinks
```

New in version 3.3.

os.symlink(*src*, *dst*, *target_is_directory=False*, ***, *dir_fd=None*)

Create a symbolic link pointing to *src* named *dst*.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as a directory if *target_is_directory* is `True` or a file symlink (the default) otherwise. On non-Windows platforms, *target_is_directory* is ignored.

This function can support paths relative to directory descriptors.

Note

On newer versions of Windows 10, unprivileged accounts can create symlinks if Developer Mode is enabled. When Developer Mode is not available/enabled, the *SeCreateSymbolicLinkPrivilege* privilege is required, or the process must be run as an administrator.

`OSError` is raised when the function is called by an unprivileged user.

Raises an auditing event `os.symlink` with arguments `src`, `dst`, `dir_fd`.

Availability: Unix, Windows.

The function is limited on Emscripten and WASI, see WebAssembly platforms for more information.

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

New in version 3.3: Added the *dir_fd* argument, and now allow *target_is_directory* on non-Windows platforms.

Changed in version 3.6: Accepts a path-like object for *src* and *dst*.

Changed in version 3.8: Added support for unelevated symlinks on Windows with Developer Mode.

os.sync()

Force write of everything to disk.

Availability: Unix.

New in version 3.3.

os.truncate(*path*, *length*)

Truncate the file corresponding to *path*, so that it is at most *length* bytes in size.

This function can support specifying a file descriptor.

Raises an auditing event `os.truncate` with arguments `path`, `length`.

Availability: Unix, Windows.

New in version 3.3.

Changed in version 3.5: Added support for Windows

Changed in version 3.6: Accepts a path-like object.

os.unlink(*path*, *, *dir_fd*=*None*)

Remove (delete) the file *path*. This function is semantically identical to **`remove()`**; the `unlink` name is its traditional Unix name. Please see the documentation for **`remove()`** for further information.

Raises an auditing event `os.remove` with arguments `path`, `dir_fd`.

New in version 3.3: The *dir_fd* parameter.

Changed in version 3.6: Accepts a path-like object.

os.utime(*path*, *times*=*None*, *, [*ns*,]*dir_fd*=*None*, *follow_symlinks*=*True*)

Set the access and modified times of the file specified by *path*.

`utime()` takes two optional parameters, *times* and *ns*. These specify the times set on *path* and are used as follows:

- If *ns* is specified, it must be a 2-tuple of the form `(atime_ns, mtime_ns)` where each member is an int expressing nanoseconds.
- If *times* is not `None`, it must be a 2-tuple of the form `(atime, mtime)` where each member is an int or float expressing seconds.
- If *times* is `None` and *ns* is unspecified, this is equivalent to specifying `ns=(atime_ns, mtime_ns)` where both times are the current time.

It is an error to specify tuples for both *times* and *ns*.

Note that the exact times you set here may not be returned by a subsequent **`stat()`** call, depending on the resolution with which your operating system records access and modification times; see **`stat()`**. The best way to preserve exact times is to use the *st_atime_ns* and *st_mtime_ns* fields from the **`os.stat()`** result object with the *ns* parameter to **`utime()`**.

This function can support specifying a file descriptor, paths

relative to directory descriptors and not following symlinks.

Raises an auditing event `os.utime` with arguments `path`, `times`, `ns`, `dir_fd`.

New in version 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd*, *follow_symlinks*, and *ns* parameters.

Changed in version 3.6: Accepts a path-like object.

os.walk(*top*, *topdown=True*, *onerror=None*, *followlinks=False*)

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple `(dirpath, dirnames, filenames)`.

dirpath is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (including symlinks to directories, and excluding `'.'` and `'..'`). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do `os.path.join(dirpath, name)`. Whether or not the lists are sorted depends on the file system. If a file is removed from or added to the *dirpath* directory during generating the lists, whether a name for that file be included is unspecified.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using **`del`** or slice assignment), and

walk() will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform **walk()** about directories the caller creates or renames before it resumes **walk()** again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the **scandir()** call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an **OSError** instance. It can report the error to continue with the walk, or raise the exception to abort the walk. Note that the filename is available as the `filename` attribute of the exception object.

By default, **walk()** will not walk down into symbolic links that resolve to directories. Set *followlinks* to `True` to visit directories pointed to by symlinks, on systems that support them.

Note

Be aware that setting *followlinks* to `True` can lead to infinite recursion if a link points to a parent directory of itself. **walk()** does not keep track of the directories it visited already.

Note

If you pass a relative pathname, don't change the current working directory between resumptions of **walk()**. **walk()** never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
```

```
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'
    print(root, "consumes", end=" ")
    print(sum(getsize(join(root, name)) for name in
    print("bytes in", len(files), "non-directory fi
    if 'CVS' in dirs:
        dirs.remove('CVS')  # don't visit CVS direc
```

In the next example (simple implementation of **shutil.rmtree()**), walking the tree bottom-up is essential, **rmdir()** doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory na
# assuming there are no symbolic links.
# CAUTION:  This is dangerous!  For example, if top
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
```

Raises an auditing event `os.walk` with arguments `top`, `topdown`, `onerror`, `followlinks`.

Changed in version 3.5: This function now calls **os.scandir()** instead of **os.listdir()**, making it faster by reducing the number of calls to **os.stat()**.

Changed in version 3.6: Accepts a path-like object.

os.fwalk(*top='.'*, *topdown=True*, *onerror=None*, ***, *follow_symlinks=False*, *dir_fd=None*)

This behaves exactly like **walk()**, except that it yields a 4-tuple `(dirpath, dirnames, filenames, dirfd)`, and it supports `dir_fd`.

dirpath, *dirnames* and *filenames* are identical to **`walk()`** output, and *dirfd* is a file descriptor referring to the directory *dirpath*.

This function always supports paths relative to directory descriptors and not following symlinks. Note however that, unlike other functions, the **`fwalk()`** default value for *follow_symlinks* is `False`.

Note

Since **`fwalk()`** yields file descriptors, those are only valid until the next iteration step, so you should duplicate them (e.g. with **`dup()`**) if you want to keep them longer.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
for root, dirs, files, rootfd in os.fwalk('python/L
    print(root, "consumes", end="")
    print(sum([os.stat(name, dir_fd=rootfd).st_size
          end="")
    print("bytes in", len(files), "non-directory fi
    if 'CVS' in dirs:
        dirs.remove('CVS')  # don't visit CVS direc
```

In the next example, walking the tree bottom-up is essential: **`rmdir()`** doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory na
# assuming there are no symbolic links.
# CAUTION:  This is dangerous!  For example, if top
# could delete all your disk files.
import os
for root, dirs, files, rootfd in os.fwalk(top, topd
    for name in files:
        os.unlink(name, dir_fd=rootfd)
```

```
        for name in dirs:
            os.rmdir(name, dir_fd=rootfd)
```

Raises an auditing event `os.fwalk` with arguments `top`, `topdown`, `onerror`, `follow_symlinks`, `dir_fd`.

Availability: Unix.

New in version 3.3.

Changed in version 3.6: Accepts a path-like object.

Changed in version 3.7: Added support for **`bytes`** paths.

os.memfd_create(*name*[, *flags*=*os.MFD_CLOEXEC*])

Create an anonymous file and return a file descriptor that refers to it. *flags* must be one of the `os.MFD_*` constants available on the system (or a bitwise ORed combination of them). By default, the new file descriptor is non-inheritable.

The name supplied in *name* is used as a filename and will be displayed as the target of the corresponding symbolic link in the directory `/proc/self/fd/`. The displayed name is always prefixed with `memfd:` and serves only for debugging purposes. Names do not affect the behavior of the file descriptor, and as such multiple files can have the same name without any side effects.

Availability: Linux >= 3.17 with glibc >= 2.27.

New in version 3.8.

os.MFD_CLOEXEC
os.MFD_ALLOW_SEALING
os.MFD_HUGETLB
os.MFD_HUGE_SHIFT
os.MFD_HUGE_MASK
os.MFD_HUGE_64KB
os.MFD_HUGE_512KB
os.MFD_HUGE_1MB

os.MFD_HUGE_2MB
os.MFD_HUGE_8MB
os.MFD_HUGE_16MB
os.MFD_HUGE_32MB
os.MFD_HUGE_256MB
os.MFD_HUGE_512MB
os.MFD_HUGE_1GB
os.MFD_HUGE_2GB
os.MFD_HUGE_16GB

These flags can be passed to **memfd_create()**.

Availability: Linux >= 3.17 with glibc >= 2.27

The MFD_HUGE* flags are only available since Linux 4.14.

New in version 3.8.

os.eventfd(*initval*[, *flags*=*os.EFD_CLOEXEC*])

Create and return an event file descriptor. The file descriptors supports raw **read()** and **write()** with a buffer size of 8, **select()**, **poll()** and similar. See man page *eventfd(2)* for more information. By default, the new file descriptor is non-inheritable.

initval is the initial value of the event counter. The initial value must be an 32 bit unsigned integer. Please note that the initial value is limited to a 32 bit unsigned int although the event counter is an unsigned 64 bit integer with a maximum value of 2^{64}-2.

flags can be constructed from **EFD_CLOEXEC**, **EFD_NONBLOCK**, and **EFD_SEMAPHORE**.

If **EFD_SEMAPHORE** is specified and the event counter is non-zero, **eventfd_read()** returns 1 and decrements the counter by one.

If **EFD_SEMAPHORE** is not specified and the event counter is non-zero, **eventfd_read()** returns the current event

counter value and resets the counter to zero.

If the event counter is zero and **EFD_NONBLOCK** is not specified, **eventfd_read()** blocks.

eventfd_write() increments the event counter. Write blocks if the write operation would increment the counter to a value larger than 2^{64}-2.

Example:

```
import os

# semaphore with start value '1'
fd = os.eventfd(1, os.EFD_SEMAPHORE | os.EFC_CLOEXE
try:
    # acquire semaphore
    v = os.eventfd_read(fd)
    try:
        do_work()
    finally:
        # release semaphore
        os.eventfd_write(fd, v)
finally:
    os.close(fd)
```

Availability: Linux >= 2.6.27 with glibc >= 2.8

New in version 3.10.

os.eventfd_read(*fd*)

Read value from an **eventfd()** file descriptor and return a 64 bit unsigned int. The function does not verify that *fd* is an **eventfd()**.

Availability: Linux >= 2.6.27

New in version 3.10.

os.eventfd_write(*fd*, *value*)

Add value to an **`eventfd()`** file descriptor. *value* must be a 64 bit unsigned int. The function does not verify that *fd* is an **`eventfd()`**.

Availability: Linux >= 2.6.27

New in version 3.10.

os.EFD_CLOEXEC

Set close-on-exec flag for new **`eventfd()`** file descriptor.

Availability: Linux >= 2.6.27

New in version 3.10.

os.EFD_NONBLOCK

Set **`O_NONBLOCK`** status flag for new **`eventfd()`** file descriptor.

Availability: Linux >= 2.6.27

New in version 3.10.

os.EFD_SEMAPHORE

Provide semaphore-like semantics for reads from a **`eventfd()`** file descriptor. On read the internal counter is decremented by one.

Availability: Linux >= 2.6.30

New in version 3.10.

Linux extended attributes

New in version 3.3.

These functions are all available on Linux only.

os.getxattr(*path*, *attribute*, *, *follow_symlinks=True*)

Return the value of the extended filesystem attribute *attribute*

for *path*. *attribute* can be bytes or str (directly or indirectly through the **PathLike** interface). If it is str, it is encoded with the filesystem encoding.

This function can support specifying a file descriptor and not following symlinks.

Raises an auditing event `os.getxattr` with arguments `path`, `attribute`.

Changed in version 3.6: Accepts a path-like object for *path* and *attribute*.

os.listxattr(*path=None*, ***, *follow_symlinks=True*)

Return a list of the extended filesystem attributes on *path*. The attributes in the list are represented as strings decoded with the filesystem encoding. If *path* is `None`, **listxattr()** will examine the current directory.

This function can support specifying a file descriptor and not following symlinks.

Raises an auditing event `os.listxattr` with argument `path`.

Changed in version 3.6: Accepts a path-like object.

os.removexattr(*path*, *attribute*, ***, *follow_symlinks=True*)

Removes the extended filesystem attribute *attribute* from *path*. *attribute* should be bytes or str (directly or indirectly through the **PathLike** interface). If it is a string, it is encoded with the filesystem encoding and error handler.

This function can support specifying a file descriptor and not following symlinks.

Raises an auditing event `os.removexattr` with arguments `path`, `attribute`.

Changed in version 3.6: Accepts a path-like object for *path* and

attribute.

os.setxattr(*path*, *attribute*, *value*, *flags*=*0*, *, *follow_symlinks*=*True*)

Set the extended filesystem attribute *attribute* on *path* to *value*. *attribute* must be a bytes or str with no embedded NULs (directly or indirectly through the **PathLike** interface). If it is a str, it is encoded with the filesystem encoding and error handler. *flags* may be **XATTR_REPLACE** or **XATTR_CREATE**. If **XATTR_REPLACE** is given and the attribute does not exist, ENODATA will be raised. If **XATTR_CREATE** is given and the attribute already exists, the attribute will not be created and EEXISTS will be raised.

This function can support specifying a file descriptor and not following symlinks.

Note

A bug in Linux kernel versions less than 2.6.39 caused the flags argument to be ignored on some filesystems.

Raises an auditing event `os.setxattr` with arguments `path, attribute, value, flags`.

Changed in version 3.6: Accepts a path-like object for *path* and *attribute*.

os.XATTR_SIZE_MAX

The maximum size the value of an extended attribute can be. Currently, this is 64 KiB on Linux.

os.XATTR_CREATE

This is a possible value for the flags argument in **setxattr()**. It indicates the operation must create an attribute.

os.XATTR_REPLACE

This is a possible value for the flags argument in **setxattr()**. It indicates the operation must replace an

existing attribute.

Process Management

These functions may be used to create and manage processes.

The various **exec*** functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program's **main()**. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

os.abort()

Generate a **SIGABRT** signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of `3`. Be aware that calling this function will not call the Python signal handler registered for **SIGABRT** with **signal.signal()**.

os.add_dll_directory(*path*)

Add a path to the DLL search path.

This search path is used when resolving dependencies for imported extension modules (the module itself is resolved through **sys.path**), and also by **ctypes**.

Remove the directory by calling **close()** on the returned object or using it in a **with** statement.

See the Microsoft documentation [https://msdn.microsoft.com/44228cf2-6306-466c-8f16-f513cd3ba8b5] for more information about how DLLs are loaded.

Raises an auditing event `os.add_dll_directory` with argument `path`.

Availability: Windows.

New in version 3.8: Previous versions of CPython would resolve DLLs using the default behavior for the current process. This led to inconsistencies, such as only sometimes searching **PATH** or the current working directory, and OS functions such as `AddDllDirectory` having no effect.

In 3.8, the two primary ways DLLs are loaded now explicitly override the process-wide behavior to ensure consistency. See the porting notes for information on updating libraries.

os.execl(*path*, *arg0*, *arg1*, ...)
os.execle(*path*, *arg0*, *arg1*, ..., *env*)
os.execlp(*file*, *arg0*, *arg1*, ...)
os.execlpe(*file*, *arg0*, *arg1*, ..., *env*)
os.execv(*path*, *args*)
os.execve(*path*, *args*, *env*)
os.execvp(*file*, *args*)
os.execvpe(*file*, *args*, *env*)

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as **OSError** exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using **sys.stdout.flush()** or **os.fsync()** before calling an **exec*** function.

The "l" and "v" variants of the **exec*** functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the **execl*()** functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a

list or tuple as the *args* parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a “p” near the end (**`execlp()`**, **`execlpe()`**, **`execvp()`**, and **`execvpe()`**) will use the **`PATH`** environment variable to locate the program *file*. When the environment is being replaced (using one of the **`exec*e`** variants, discussed in the next paragraph), the new environment is used as the source of the **`PATH`** variable. The other variants, **`execl()`**, **`execle()`**, **`execv()`**, and **`execve()`**, will not use the **`PATH`** variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For **`execle()`**, **`execlpe()`**, **`execve()`**, and **`execvpe()`** (note that these all end in “e”), the *env* parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of the current process’ environment); the functions **`execl()`**, **`execlp()`**, **`execv()`**, and **`execvp()`** all cause the new process to inherit the environment of the current process.

For **`execve()`** on some platforms, *path* may also be specified as an open file descriptor. This functionality may not be supported on your platform; you can check whether or not it is available using **`os.supports_fd`**. If it is unavailable, using it will raise a **`NotImplementedError`**.

Raises an auditing event `os.exec` with arguments `path`, `args`, `env`.

Availability: Unix, Windows, not Emscripten, not WASI.

New in version 3.3: Added support for specifying *path* as an open file descriptor for **`execve()`**.

Changed in version 3.6: Accepts a path-like object.

os._exit(*n*)

Exit the process with status *n*, without calling cleanup

handlers, flushing stdio buffers, etc.

Note

The standard way to exit is `sys.exit(n)`. **`_exit()`** should normally only be used in the child process after a **`fork()`**.

The following exit codes are defined and can be used with **`_exit()`**, although they are not required. These are typically used for system programs written in Python, such as a mail server's external command delivery program.

Note

Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

os.EX_OK

Exit code that means no error occurred. May be taken from the defined value of `EXIT_SUCCESS` on some platforms. Generally has a value of zero.

Availability: Unix, Windows.

os.EX_USAGE

Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

Availability: Unix, not Emscripten, not WASI.

os.EX_DATAERR

Exit code that means the input data was incorrect.

Availability: Unix, not Emscripten, not WASI.

os.EX_NOINPUT

Exit code that means an input file did not exist or was not readable.

Availability: Unix, not Emscripten, not WASI.

os.EX_NOUSER
: Exit code that means a specified user did not exist.

  Availability: Unix, not Emscripten, not WASI.

os.EX_NOHOST
: Exit code that means a specified host did not exist.

  Availability: Unix, not Emscripten, not WASI.

os.EX_UNAVAILABLE
: Exit code that means that a required service is unavailable.

  Availability: Unix, not Emscripten, not WASI.

os.EX_SOFTWARE
: Exit code that means an internal software error was detected.

  Availability: Unix, not Emscripten, not WASI.

os.EX_OSERR
: Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

  Availability: Unix, not Emscripten, not WASI.

os.EX_OSFILE
: Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

  Availability: Unix, not Emscripten, not WASI.

os.EX_CANTCREAT
: Exit code that means a user specified output file could not be

created.

Availability: Unix, not Emscripten, not WASI.

os.EX_IOERR
: Exit code that means that an error occurred while doing I/O on some file.

  Availability: Unix, not Emscripten, not WASI.

os.EX_TEMPFAIL
: Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

  Availability: Unix, not Emscripten, not WASI.

os.EX_PROTOCOL
: Exit code that means that a protocol exchange was illegal, invalid, or not understood.

  Availability: Unix, not Emscripten, not WASI.

os.EX_NOPERM
: Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

  Availability: Unix, not Emscripten, not WASI.

os.EX_CONFIG
: Exit code that means that some kind of configuration error occurred.

  Availability: Unix, not Emscripten, not WASI.

os.EX_NOTFOUND
: Exit code that means something like "an entry was not

found".

Availability: Unix, not Emscripten, not WASI.

os.fork()

Fork a child process. Return `0` in the child and the child's process id in the parent. If an error occurs **`OSError`** is raised.

Note that some platforms including FreeBSD <= 6.3 and Cygwin have known issues when using `fork()` from a thread.

Raises an auditing event `os.fork` with no arguments.

Changed in version 3.8: Calling `fork()` in a subinterpreter is no longer supported (**`RuntimeError`** is raised).

Warning

See **`ssl`** for applications that use the SSL module with fork().

Availability: Unix, not Emscripten, not WASI.

os.forkpty()

Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of `(pid, fd)`, where *pid* is `0` in the child, the new child's process id in the parent, and *fd* is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the **`pty`** module. If an error occurs **`OSError`** is raised.

Raises an auditing event `os.forkpty` with no arguments.

Changed in version 3.8: Calling `forkpty()` in a subinterpreter is no longer supported (**`RuntimeError`** is raised).

Availability: Unix, not Emscripten, not WASI.

os.kill(*pid*, *sig*, */*)

Send signal *sig* to the process *pid*. Constants for the specific signals available on the host platform are defined in the **signal** module.

Windows: The **signal.CTRL_C_EVENT** and **signal.CTRL_BREAK_EVENT** signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for *sig* will cause the process to be unconditionally killed by the TerminateProcess API, and the exit code will be set to *sig*. The Windows version of **kill()** additionally takes process handles to be killed.

See also **signal.pthread_kill()**.

Raises an auditing event `os.kill` with arguments `pid`, `sig`.

Availability: Unix, Windows, not Emscripten, not WASI.

New in version 3.2: Windows support.

os.killpg(*pgid*, *sig*, */*)

Send the signal *sig* to the process group *pgid*.

Raises an auditing event `os.killpg` with arguments `pgid`, `sig`.

Availability: Unix, not Emscripten, not WASI.

os.nice(*increment*, */*)

Add *increment* to the process's "niceness". Return the new niceness.

Availability: Unix, not Emscripten, not WASI.

os.pidfd_open(*pid*, *flags=0*)

Return a file descriptor referring to the process *pid*. This

descriptor can be used to perform process management without races and signals. The *flags* argument is provided for future extensions; no flag values are currently defined.

See the *pidfd_open(2)* man page for more details.

Availability: Linux >= 5.3

New in version 3.9.

os.plock(*op*, */*)

Lock program segments into memory. The value of *op* (defined in `<sys/lock.h>`) determines which segments are locked.

Availability: Unix, not Emscripten, not WASI.

os.popen(*cmd*, *mode='r'*, *buffering=-1*)

Open a pipe to or from command *cmd*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is `'r'` (default) or `'w'`. The *buffering* argument have the same meaning as the corresponding argument to the built-in **`open()`** function. The returned file object reads or writes text strings rather than bytes.

The `close` method returns **`None`** if the subprocess exited successfully, or the subprocess's return code if there was an error. On POSIX systems, if the return code is positive it represents the return value of the process left-shifted by one byte. If the return code is negative, the process was terminated by the signal given by the negated value of the return code. (For example, the return value might be `-signal.SIGKILL` if the subprocess was killed.) On Windows systems, the return value contains the signed integer return code from the child process.

On Unix, **`waitstatus_to_exitcode()`** can be used to convert the `close` method result (exit status) into an exit code if it is not `None`. On Windows, the `close` method

result is directly the exit code (or `None`).

This is implemented using **`subprocess.Popen`**; see that class's documentation for more powerful ways to manage and communicate with subprocesses.

Availability: not Emscripten, not WASI.

Note

The Python UTF-8 Mode affects encodings used for *cmd* and pipe contents.

`popen()` is a simple wrapper around **`subprocess.Popen`**. Use **`subprocess.Popen`** or **`subprocess.run()`** to control options like encodings.

os.posix_spawn(*path*, *argv*, *env*, ***, *file_actions=None*, *setpgroup=None*, *resetids=False*, *setsid=False*, *setsigmask=()*, *setsigdef=()*, *scheduler=None*)

Wraps the **`posix_spawn()`** C library API for use from Python.

Most users should use **`subprocess.run()`** instead of **`posix_spawn()`**.

The positional-only arguments *path*, *args*, and *env* are similar to **`execve()`**.

The *path* parameter is the path to the executable file. The *path* should contain a directory. Use **`posix_spawnp()`** to pass an executable file without directory.

The *file_actions* argument may be a sequence of tuples describing actions to take on specific file descriptors in the child process between the C library implementation's **`fork()`** and **`exec()`** steps. The first item in each tuple must be one of the three type indicator listed below describing the remaining tuple elements:

os.POSIX_SPAWN_OPEN

(`os.POSIX_SPAWN_OPEN`, *fd*, *path*, *flags*, *mode*)

Performs `os.dup2(os.open(path, flags, mode), fd)`.

os.POSIX_SPAWN_CLOSE

(`os.POSIX_SPAWN_CLOSE`, *fd*)

Performs `os.close(fd)`.

os.POSIX_SPAWN_DUP2

(`os.POSIX_SPAWN_DUP2`, *fd*, *new fd*)

Performs `os.dup2(fd, new_fd)`.

These tuples correspond to the C library **`posix_spawn_file_actions_addopen()`**, **`posix_spawn_file_actions_addclose()`**, and **`posix_spawn_file_actions_adddup2()`** API calls used to prepare for the **`posix_spawn()`** call itself.

The *setpgroup* argument will set the process group of the child to the value specified. If the value specified is 0, the child's process group ID will be made the same as its process ID. If the value of *setpgroup* is not set, the child will inherit the parent's process group ID. This argument corresponds to the C library **`POSIX_SPAWN_SETPGROUP`** flag.

If the *resetids* argument is `True` it will reset the effective UID and GID of the child to the real UID and GID of the parent process. If the argument is `False`, then the child retains the effective UID and GID of the parent. In either case, if the set-user-ID and set-group-ID permission bits are enabled on the executable file, their effect will override the setting of the effective UID and GID. This argument corresponds to the C library **`POSIX_SPAWN_RESETIDS`** flag.

If the *setsid* argument is `True`, it will create a new session ID for `posix_spawn`. *setsid* requires **`POSIX_SPAWN_SETSID`**

or **POSIX_SPAWN_SETSID_NP** flag. Otherwise, **NotImplementedError** is raised.

The *setsigmask* argument will set the signal mask to the signal set specified. If the parameter is not used, then the child inherits the parent's signal mask. This argument corresponds to the C library **POSIX_SPAWN_SETSIGMASK** flag.

The *sigdef* argument will reset the disposition of all signals in the set specified. This argument corresponds to the C library **POSIX_SPAWN_SETSIGDEF** flag.

The *scheduler* argument must be a tuple containing the (optional) scheduler policy and an instance of **sched_param** with the scheduler parameters. A value of `None` in the place of the scheduler policy indicates that is not being provided. This argument is a combination of the C library **POSIX_SPAWN_SETSCHEDPARAM** and **POSIX_SPAWN_SETSCHEDULER** flags.

Raises an auditing event `os.posix_spawn` with arguments `path`, `argv`, `env`.

New in version 3.8.

Availability: Unix, not Emscripten, not WASI.

os.posix_spawnp(*path*, *argv*, *env*, ***, *file_actions=None*, *setpgroup=None*, *resetids=False*, *setsid=False*, *setsigmask=()*, *setsigdef=()*, *scheduler=None*)

Wraps the **posix_spawnp()** C library API for use from Python.

Similar to **posix_spawn()** except that the system searches for the *executable* file in the list of directories specified by the **PATH** environment variable (in the same way as for `execvp(3)`).

Raises an auditing event `os.posix_spawn` with arguments `path`, `argv`, `env`.

New in version 3.8.

Availability: POSIX, not Emscripten, not WASI.

See **posix_spawn()** documentation.

os.register_at_fork(*, *before*=*None*, *after_in_parent*=*None*, *after_in_child*=*None*)

Register callables to be executed when a new child process is forked using **os.fork()** or similar process cloning APIs. The parameters are optional and keyword-only. Each specifies a different call point.

- *before* is a function called before forking a child process.
- *after_in_parent* is a function called from the parent process after forking a child process.
- *after_in_child* is a function called from the child process.

These calls are only made if control is expected to return to the Python interpreter. A typical **subprocess** launch will not trigger them as the child is not going to re-enter the interpreter.

Functions registered for execution before forking are called in reverse registration order. Functions registered for execution after forking (either in the parent or in the child) are called in registration order.

Note that **fork()** calls made by third-party C code may not call those functions, unless it explicitly calls **PyOS_BeforeFork()**, **PyOS_AfterFork_Parent()** and **PyOS_AfterFork_Child()**.

There is no way to unregister a function.

Availability: Unix, not Emscripten, not WASI.

New in version 3.7.

os.spawnl(*mode*, *path*, ...)
os.spawnle(*mode*, *path*, ..., *env*)
os.spawnlp(*mode*, *file*, ...)
os.spawnlpe(*mode*, *file*, ..., *env*)
os.spawnv(*mode*, *path*, *args*)
os.spawnve(*mode*, *path*, *args*, *env*)
os.spawnvp(*mode*, *file*, *args*)
os.spawnvpe(*mode*, *file*, *args*, *env*)

Execute the program *path* in a new process.

(Note that the **subprocess** module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the Replacing Older Functions with the subprocess Module section.)

If *mode* is **P_NOWAIT**, this function returns the process id of the new process; if *mode* is **P_WAIT**, returns the process's exit code if it exits normally, or `-signal`, where *signal* is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the **waitpid()** function.

Note on VxWorks, this function doesn't return `-signal` when the new process is killed. Instead it raises OSError exception.

The "l" and "v" variants of the **spawn*** functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the **spawnl*()** functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second "p" near the end

(**spawnlp()**, **spawnlpe()**, **spawnvp()**, and **spawnvpe()**) will use the **PATH** environment variable to locate the program *file*. When the environment is being replaced (using one of the **spawn*e** variants, discussed in the next paragraph), the new environment is used as the source of the **PATH** variable. The other variants, **spawnl()**, **spawnle()**, **spawnv()**, and **spawnve()**, will not use the **PATH** variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For **spawnle()**, **spawnlpe()**, **spawnve()**, and **spawnvpe()** (note that these all end in "e"), the *env* parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process' environment); the functions **spawnl()**, **spawnlp()**, **spawnv()**, and **spawnvp()** all cause the new process to inherit the environment of the current process. Note that keys and values in the *env* dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of `127`.

As an example, the following calls to **spawnlp()** and **spawnvpe()** are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/d

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Raises an auditing event `os.spawn` with arguments `mode`, `path`, `args`, `env`.

Availability: Unix, Windows, not Emscripten, not WASI.

spawnlp(), **spawnlpe()**, **spawnvp()** and **spawnvpe()** are not available on Windows. **spawnle()** and **spawnve()** are not thread-safe on Windows; we advise you to use the **subprocess** module instead.

Changed in version 3.6: Accepts a path-like object.

os.P_NOWAIT
os.P_NOWAITO

Possible values for the *mode* parameter to the **spawn*** family of functions. If either of these values is given, the **spawn*()** functions will return as soon as the new process has been created, with the process id as the return value.

Availability: Unix, Windows.

os.P_WAIT

Possible value for the *mode* parameter to the **spawn*** family of functions. If this is given as *mode*, the **spawn*()** functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or `-signal` if a signal kills the process.

Availability: Unix, Windows.

os.P_DETACH
os.P_OVERLAY

Possible values for the *mode* parameter to the **spawn*** family of functions. These are less portable than those listed above. **P_DETACH** is similar to **P_NOWAIT**, but the new process is detached from the console of the calling process. If **P_OVERLAY** is used, the current process will be replaced; the **spawn*** function will not return.

Availability: Windows.

os.startfile(*path*[, *operation*][, *arguments*][, *cwd*][, *show_cmd*])

Start a file with its associated application.

When *operation* is not specified or `'open'`, this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the **start** command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another *operation* is given, it must be a “command verb” that specifies what should be done with the file. Common verbs documented by Microsoft are `'print'` and `'edit'` (to be used on files) as well as `'explore'` and `'find'` (to be used on directories).

When launching an application, specify *arguments* to be passed as a single string. This argument may have no effect when using this function to launch a document.

The default working directory is inherited, but may be overridden by the *cwd* argument. This should be an absolute path. A relative *path* will be resolved against this argument.

Use *show_cmd* to override the default window style. Whether this has any effect will depend on the application being launched. Values are integers as supported by the Win32 **`ShellExecute()`** function.

`startfile()` returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application’s exit status. The *path* parameter is relative to the current directory or *cwd*. If you want to use an absolute path, make sure the first character is not a slash (`'/'`) Use **`pathlib`** or the **`os.path.normpath()`** function to ensure that paths are properly encoded for Win32.

To reduce interpreter startup overhead, the Win32 **`ShellExecute()`** function is not resolved until this function is first called. If the function cannot be resolved, **`NotImplementedError`** will be raised.

Raises an auditing event `os.startfile` with arguments `path, operation`.

Raises an auditing event `os.startfile/2` with arguments `path, operation, arguments, cwd, show_cmd`.

Availability: Windows.

Changed in version 3.10: Added the *arguments*, *cwd* and *show_cmd* arguments, and the `os.startfile/2` audit event.

os.system(*command*)

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function **`system()`**, and has the same limitations. Changes to **`sys.stdin`**, etc. are not reflected in the environment of the executed command. If *command* generates any output, it will be sent to the interpreter standard output stream. The C standard does not specify the meaning of the return value of the C function, so the return value of the Python function is system-dependent.

On Unix, the return value is the exit status of the process encoded in the format specified for **`wait()`**.

On Windows, the return value is that returned by the system shell after running *command*. The shell is given by the Windows environment variable **`COMSPEC`**: it is usually **cmd.exe**, which returns the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The **`subprocess`** module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the Replacing Older Functions with the subprocess Module section in the **`subprocess`** documentation for some helpful recipes.

On Unix, **`waitstatus_to_exitcode()`** can be used to convert the result (exit status) into an exit code. On Windows, the result is directly the exit code.

Raises an auditing event `os.system` with argument `command`.

Availability: Unix, Windows, not Emscripten, not WASI.

os.times()

Returns the current global process times. The return value is an object with five attributes:

- **user** - user time
- **system** - system time
- **children_user** - user time of all child processes
- **children_system** - system time of all child processes
- **elapsed** - elapsed real time since a fixed point in the past

For backwards compatibility, this object also behaves like a five-tuple containing **user**, **system**, **children_user**, **children_system**, and **elapsed** in that order.

See the Unix manual page *times(2)* and times(3) [https://www.freebsd.org/cgi/man.cgi?time(3)] manual page on Unix or the GetProcessTimes MSDN [https://docs.microsoft.com/windows/win32/api/processthreadsapi/nf-processthreadsapi-getprocesstimes] on Windows. On Windows, only **user** and **system** are known; the other attributes are zero.

Availability: Unix, Windows.

Changed in version 3.3: Return type changed from a tuple to a tuple-like object with named attributes.

os.wait()

Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

If there are no children that could be waited for, **ChildProcessError** is raised.

waitstatus_to_exitcode() can be used to convert the exit status into an exit code.

Availability: Unix, not Emscripten, not WASI.

See also

The other **wait*()** functions documented below can be used to wait for the completion of a specific child process and have more options. **waitpid()** is the only one also available on Windows.

os.waitid(*idtype*, *id*, *options*, */*)

Wait for the completion of a child process.

idtype can be **P_PID**, **P_PGID**, **P_ALL**, or (on Linux) **P_PIDFD**. The interpretation of *id* depends on it; see their individual descriptions.

options is an OR combination of flags. At least one of **WEXITED**, **WSTOPPED** or **WCONTINUED** is required; **WNOHANG** and **WNOWAIT** are additional optional flags.

The return value is an object representing the data contained in the **siginfo_t** structure with the following attributes:

- **si_pid** (process ID)
- **si_uid** (real user ID of the child)
- **si_signo** (always **SIGCHLD**)
- **si_status** (the exit status or signal number, depending on **si_code**)
- **si_code** (see **CLD_EXITED** for possible values)

If **WNOHANG** is specified and there are no matching children in the requested state, `None` is returned. Otherwise, if there are no matching children that could be waited for, **ChildProcessError** is raised.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.waitpid(*pid*, *options*, */*)

The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id *pid*, and return a tuple containing its process id and exit status indication (encoded as for **`wait()`**). The semantics of the call are affected by the value of the integer *options*, which should be `0` for normal operation.

If *pid* is greater than `0`, **`waitpid()`** requests status information for that specific process. If *pid* is `0`, the request is for the status of any child in the process group of the current process. If *pid* is `-1`, the request pertains to any child of the current process. If *pid* is less than `-1`, status is requested for any process in the process group `-pid` (the absolute value of *pid*).

options is an OR combination of flags. If it contains **`WNOHANG`** and there are no matching children in the requested state, `(0, 0)` is returned. Otherwise, if there are no matching children that could be waited for, **`ChildProcessError`** is raised. Other options that can be used are **`WUNTRACED`** and **`WCONTINUED`**.

On Windows: Wait for completion of a process given by process handle *pid*, and return a tuple containing *pid*, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A *pid* less than or equal to `0` has no special meaning on Windows, and raises an exception. The value of integer *options* has no effect. *pid* can refer to any process whose id is known, not necessarily a child process. The **`spawn*`** functions called with **`P_NOWAIT`** return suitable process handles.

`waitstatus_to_exitcode()` can be used to convert the exit status into an exit code.

Availability: Unix, Windows, not Emscripten, not WASI.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now

retries the system call instead of raising an **InterruptedError** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

os.wait3(*options*)

Similar to **waitpid()**, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to **resource.getrusage()** for details on resource usage information. The *options* argument is the same as that provided to **waitpid()** and **wait4()**.

waitstatus_to_exitcode() can be used to convert the exit status into an exitcode.

Availability: Unix, not Emscripten, not WASI.

os.wait4(*pid*, *options*)

Similar to **waitpid()**, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to **resource.getrusage()** for details on resource usage information. The arguments to **wait4()** are the same as those provided to **waitpid()**.

waitstatus_to_exitcode() can be used to convert the exit status into an exitcode.

Availability: Unix, not Emscripten, not WASI.

os.P_PID
os.P_PGID
os.P_ALL
os.P_PIDFD

These are the possible values for *idtype* in **waitid()**. They affect how *id* is interpreted:

- **P_PID** - wait for the child whose PID is *id*.
- **P_PGID** - wait for any child whose progress group ID is

id.

- **P_ALL** - wait for any child; *id* is ignored.
- **P_PIDFD** - wait for the child identified by the file descriptor *id* (a process file descriptor created with **pidfd_open()**).

Availability: Unix, not Emscripten, not WASI.

Note

P_PIDFD is only available on Linux >= 5.4.

New in version 3.3.

New in version 3.9: The **P_PIDFD** constant.

os.WCONTINUED

This *options* flag for **waitpid()**, **wait3()**, **wait4()**, and **waitid()** causes child processes to be reported if they have been continued from a job control stop since they were last reported.

Availability: Unix, not Emscripten, not WASI.

os.WEXITED

This *options* flag for **waitid()** causes child processes that have terminated to be reported.

The other `wait*` functions always report children that have terminated, so this option is not available for them.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.WSTOPPED

This *options* flag for **waitid()** causes child processes that have been stopped by the delivery of a signal to be reported.

This option is not available for the other `wait*` functions.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

os.WUNTRACED

This *options* flag for **`waitpid()`**, **`wait3()`**, and **`wait4()`** causes child processes to also be reported if they have been stopped but their current state has not been reported since they were stopped.

This option is not available for **`waitid()`**.

Availability: Unix, not Emscripten, not WASI.

os.WNOHANG

This *options* flag causes **`waitpid()`**, **`wait3()`**, **`wait4()`**, and **`waitid()`** to return right away if no child process status is available immediately.

Availability: Unix, not Emscripten, not WASI.

os.WNOWAIT

This *options* flag causes **`waitid()`** to leave the child in a waitable state, so that a later **`wait*()`** call can be used to retrieve the child status information again.

This option is not available for the other `wait*` functions.

Availability: Unix, not Emscripten, not WASI.

os.CLD_EXITED
os.CLD_KILLED
os.CLD_DUMPED
os.CLD_TRAPPED
os.CLD_STOPPED
os.CLD_CONTINUED

These are the possible values for **`si_code`** in the result returned by **`waitid()`**.

Availability: Unix, not Emscripten, not WASI.

New in version 3.3.

Changed in version 3.9: Added **CLD_KILLED** and **CLD_STOPPED** values.

os.waitstatus_to_exitcode(*status*)

Convert a wait status to an exit code.

On Unix:

- If the process exited normally (if `WIFEXITED(status)` is true), return the process exit status (return `WEXITSTATUS(status)`): result greater than or equal to 0.
- If the process was terminated by a signal (if `WIFSIGNALED(status)` is true), return `-signum` where *signum* is the number of the signal that caused the process to terminate (return `-WTERMSIG(status)`): result less than 0.
- Otherwise, raise a **ValueError**.

On Windows, return *status* shifted right by 8 bits.

On Unix, if the process is being traced or if **waitpid()** was called with **WUNTRACED** option, the caller must first check if `WIFSTOPPED(status)` is true. This function must not be called if `WIFSTOPPED(status)` is true.

See also

WIFEXITED(), **WEXITSTATUS()**, **WIFSIGNALED()**, **WTERMSIG()**, **WIFSTOPPED()**, **WSTOPSIG()** functions.

Availability: Unix, Windows, not Emscripten, not WASI.

New in version 3.9.

The following functions take a process status code as returned by **system()**, **wait()**, or **waitpid()** as a parameter. They may be used to determine the disposition of a process.

os.WCOREDUMP(*status*, */*)

Return `True` if a core dump was generated for the process, otherwise return `False`.

This function should be employed only if **`WIFSIGNALED()`** is true.

Availability: Unix, not Emscripten, not WASI.

os.WIFCONTINUED(*status*)

Return `True` if a stopped child has been resumed by delivery of **`SIGCONT`** (if the process has been continued from a job control stop), otherwise return `False`.

See **`WCONTINUED`** option.

Availability: Unix, not Emscripten, not WASI.

os.WIFSTOPPED(*status*)

Return `True` if the process was stopped by delivery of a signal, otherwise return `False`.

`WIFSTOPPED()` only returns `True` if the **`waitpid()`** call was done using **`WUNTRACED`** option or when the process is being traced (see *ptrace(2)*).

Availability: Unix, not Emscripten, not WASI.

os.WIFSIGNALED(*status*)

Return `True` if the process was terminated by a signal, otherwise return `False`.

Availability: Unix, not Emscripten, not WASI.

os.WIFEXITED(*status*)

Return `True` if the process exited terminated normally, that is, by calling `exit()` or `_exit()`, or by returning from `main()`; otherwise return `False`.

Availability: Unix, not Emscripten, not WASI.

os.WEXITSTATUS(*status*)

Return the process exit status.

This function should be employed only if **`WIFEXITED()`** is true.

Availability: Unix, not Emscripten, not WASI.

os.WSTOPSIG(*status*)

Return the signal which caused the process to stop.

This function should be employed only if **`WIFSTOPPED()`** is true.

Availability: Unix, not Emscripten, not WASI.

os.WTERMSIG(*status*)

Return the number of the signal that caused the process to terminate.

This function should be employed only if **`WIFSIGNALED()`** is true.

Availability: Unix, not Emscripten, not WASI.

Interface to the scheduler

These functions control how a process is allocated CPU time by the operating system. They are only available on some Unix platforms. For more detailed information, consult your Unix manpages.

New in version 3.3.

The following scheduling policies are exposed if they are supported by the operating system.

os.SCHED_OTHER

The default scheduling policy.

os.SCHED_BATCH

Scheduling policy for CPU-intensive processes that tries to preserve interactivity on the rest of the computer.

os.SCHED_IDLE

Scheduling policy for extremely low priority background tasks.

os.SCHED_SPORADIC

Scheduling policy for sporadic server programs.

os.SCHED_FIFO

A First In First Out scheduling policy.

os.SCHED_RR

A round-robin scheduling policy.

os.SCHED_RESET_ON_FORK

This flag can be OR'ed with any other scheduling policy. When a process with this flag set forks, its child's scheduling policy and priority are reset to the default.

class os.sched_param(*sched_priority*)

This class represents tunable scheduling parameters used in **`sched_setparam()`**, **`sched_setscheduler()`**, and **`sched_getparam()`**. It is immutable.

At the moment, there is only one possible parameter:

sched_priority

The scheduling priority for a scheduling policy.

os.sched_get_priority_min(*policy*)

Get the minimum priority value for *policy*. *policy* is one of the scheduling policy constants above.

os.sched_get_priority_max(*policy*)

Get the maximum priority value for *policy*. *policy* is one of the scheduling policy constants above.

os.sched_setscheduler(*pid*, *policy*, *param*, */*)

Set the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. *policy* is one of the scheduling policy constants above. *param* is a **`sched_param`** instance.

os.sched_getscheduler(*pid*, */*)

Return the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. The result is one of the scheduling policy constants above.

os.sched_setparam(*pid*, *param*, */*)

Set the scheduling parameters for the process with PID *pid*. A *pid* of 0 means the calling process. *param* is a **`sched_param`** instance.

os.sched_getparam(*pid*, */*)

Return the scheduling parameters as a **`sched_param`** instance for the process with PID *pid*. A *pid* of 0 means the calling process.

os.sched_rr_get_interval(*pid*, */*)

Return the round-robin quantum in seconds for the process with PID *pid*. A *pid* of 0 means the calling process.

os.sched_yield()

Voluntarily relinquish the CPU.

os.sched_setaffinity(*pid*, *mask*, */*)

Restrict the process with PID *pid* (or the current process if zero) to a set of CPUs. *mask* is an iterable of integers representing the set of CPUs to which the process should be restricted.

os.sched_getaffinity(*pid*, */*)

Return the set of CPUs the process with PID *pid* (or the current process if zero) is restricted to.

Miscellaneous System Information

os.confstr(*name*, */*)

Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, **`ValueError`** is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an **`OSError`** is raised with **`errno.EINVAL`** for the error number.

Availability: Unix.

os.confstr_names

Dictionary mapping names accepted by **`confstr()`** to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

os.cpu_count()

Return the number of CPUs in the system. Returns `None` if

undetermined.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with `len(os.sched_getaffinity(0))`

New in version 3.4.

os.getloadavg()

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises **`OSError`** if the load average was unobtainable.

Availability: Unix.

os.sysconf(*name*, /)

Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, `-1` is returned. The comments regarding the *name* parameter for **`confstr()`** apply here as well; the dictionary that provides information on the known names is given by `sysconf_names`.

Availability: Unix.

os.sysconf_names

Dictionary mapping names accepted by **`sysconf()`** to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

Changed in version 3.11: Add `'SC_MINSIGSTKSZ'` name.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the **`os.path`**

module.

os.curdir

The constant string used by the operating system to refer to the current directory. This is `'.'` for Windows and POSIX. Also available via **`os.path`**.

os.pardir

The constant string used by the operating system to refer to the parent directory. This is `'..'` for Windows and POSIX. Also available via **`os.path`**.

os.sep

The character used by the operating system to separate pathname components. This is `'/'` for POSIX and `'\\'` for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames — use **`os.path.split()`** and **`os.path.join()`** — but it is occasionally useful. Also available via **`os.path`**.

os.altsep

An alternative character used by the operating system to separate pathname components, or `None` if only one separator character exists. This is set to `'/'` on Windows systems where `sep` is a backslash. Also available via **`os.path`**.

os.extsep

The character which separates the base filename from the extension; for example, the `'.'` in `os.py`. Also available via **`os.path`**.

os.pathsep

The character conventionally used by the operating system to separate search path components (as in **`PATH`**), such as `':'` for POSIX or `';'` for Windows. Also available via **`os.path`**.

os.defpath

The default search path used by **exec*p*** and **spawn*p*** if the environment doesn't have a `'PATH'` key. Also available via **os.path**.

os.linesep

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as `'\n'` for POSIX, or multiple characters, for example, `'\r\n'` for Windows. Do not use *os.linesep* as a line terminator when writing files opened in text mode (the default); use a single `'\n'` instead, on all platforms.

os.devnull

The file path of the null device. For example: `'/dev/null'` for POSIX, `'nul'` for Windows. Also available via **os.path**.

os.RTLD_LAZY
os.RTLD_NOW
os.RTLD_GLOBAL
os.RTLD_LOCAL
os.RTLD_NODELETE
os.RTLD_NOLOAD
os.RTLD_DEEPBIND

Flags for use with the **setdlopenflags()** and **getdlopenflags()** functions. See the Unix manual page *dlopen(3)* for what the different flags mean.

New in version 3.3.

Random numbers

os.getrandom(*size*, *flags*=*0*)

Get up to *size* random bytes. The function can return less bytes than requested.

These bytes can be used to seed user-space random number generators or for cryptographic purposes.

`getrandom()` relies on entropy gathered from device drivers and other sources of environmental noise. Unnecessarily reading large quantities of data will have a negative impact on other users of the `/dev/random` and `/dev/urandom` devices.

The flags argument is a bit mask that can contain zero or more of the following values ORed together: **`os.GRND_RANDOM`** and **`GRND_NONBLOCK`**.

See also the Linux getrandom() manual page [https://man7.org/linux/man-pages/man2/getrandom.2.html].

Availability: Linux >= 3.17.

New in version 3.6.

os.urandom(*size*, */*)

Return a bytestring of *size* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation.

On Linux, if the `getrandom()` syscall is available, it is used in blocking mode: block until the system urandom entropy pool is initialized (128 bits of entropy are collected by the kernel). See the **PEP 524** [https://peps.python.org/pep-0524/] for the rationale. On Linux, the **`getrandom()`** function can be used to get random bytes in non-blocking mode (using the **`GRND_NONBLOCK`** flag) or to poll until the system urandom entropy pool is initialized.

On a Unix-like system, random bytes are read from the `/dev/urandom` device. If the `/dev/urandom` device is not available or not readable, the **`NotImplementedError`** exception is raised.

On Windows, it will use `BCryptGenRandom()`.

See also

The **secrets** module provides higher level functions. For an easy-to-use interface to the random number generator provided by your platform, please see **random.SystemRandom**.

Changed in version 3.6.0: On Linux, `getrandom()` is now used in blocking mode to increase the security.

Changed in version 3.5.2: On Linux, if the `getrandom()` syscall blocks (the urandom entropy pool is not initialized yet), fall back on reading `/dev/urandom`.

Changed in version 3.5: On Linux 3.17 and newer, the `getrandom()` syscall is now used when available. On OpenBSD 5.6 and newer, the C `getentropy()` function is now used. These functions avoid the usage of an internal file descriptor.

Changed in version 3.11: On Windows, `BCryptGenRandom()` is used instead of `CryptGenRandom()` which is deprecated.

os.GRND_NONBLOCK

By default, when reading from `/dev/random`, **getrandom()** blocks if no random bytes are available, and when reading from `/dev/urandom`, it blocks if the entropy pool has not yet been initialized.

If the **GRND_NONBLOCK** flag is set, then **getrandom()** does not block in these cases, but instead immediately raises **BlockingIOError**.

New in version 3.6.

os.GRND_RANDOM

If this bit is set, then random bytes are drawn from the `/dev/random` pool instead of the `/dev/urandom` pool.

New in version 3.6.

`io` — Core tools for working with streams

Source code: Lib/io.py [https://github.com/python/cpython/tree/3.11/Lib/io.py]

Overview

The `io` module provides Python's main facilities for dealing with various types of I/O. There are three main types of I/O: *text I/O*, *binary I/O* and *raw I/O*. These are generic categories, and various backing stores can be used for each of them. A concrete object belonging to any of these categories is called a file object. Other common terms are *stream* and *file-like object*.

Independent of its category, each concrete stream object will also have various capabilities: it can be read-only, write-only, or read-write. It can also allow arbitrary random access (seeking forwards or backwards to any location), or only sequential access (for example in the case of a socket or pipe).

All streams are careful about the type of data you give to them. For example giving a `str` object to the `write()` method of a binary stream will raise a `TypeError`. So will giving a `bytes` object to the `write()` method of a text stream.

Changed in version 3.3: Operations that used to raise `IOError` now raise `OSError`, since `IOError` is now an alias of `OSError`.

Text I/O

Text I/O expects and produces `str` objects. This means that whenever the backing store is natively made of bytes (such as in the case of a file), encoding and decoding of data is made transparently

as well as optional translation of platform-specific newline characters.

The easiest way to create a text stream is with **`open()`**, optionally specifying an encoding:

```
f = open("myfile.txt", "r", encoding="utf-8")
```

In-memory text streams are also available as **`StringIO`** objects:

```
f = io.StringIO("some initial text data")
```

The text stream API is described in detail in the documentation of **`TextIOBase`**.

Binary I/O

Binary I/O (also called *buffered I/O*) expects bytes-like objects and produces **`bytes`** objects. No encoding, decoding, or newline translation is performed. This category of streams can be used for all kinds of non-text data, and also when manual control over the handling of text data is desired.

The easiest way to create a binary stream is with **`open()`** with `'b'` in the mode string:

```
f = open("myfile.jpg", "rb")
```

In-memory binary streams are also available as **`BytesIO`** objects:

```
f = io.BytesIO(b"some initial binary data: \x00\x01")
```

The binary stream API is described in detail in the docs of **`BufferedIOBase`**.

Other library modules may provide additional ways to create text or binary streams. See **`socket.socket.makefile()`** for example.

Raw I/O

Raw I/O (also called *unbuffered I/O*) is generally used as a low-level

building-block for binary and text streams; it is rarely useful to directly manipulate a raw stream from user code. Nevertheless, you can create a raw stream by opening a file in binary mode with buffering disabled:

```
f = open("myfile.jpg", "rb", buffering=0)
```

The raw stream API is described in detail in the docs of **`RawIOBase`**.

Text Encoding

The default encoding of **`TextIOWrapper`** and **`open()`** is locale-specific (**`locale.getencoding()`**).

However, many developers forget to specify the encoding when opening text files encoded in UTF-8 (e.g. JSON, TOML, Markdown, etc…) since most Unix platforms use UTF-8 locale by default. This causes bugs because the locale encoding is not UTF-8 for most Windows users. For example:

```
# May not work on Windows when non-ASCII characters in t
with open("README.md") as f:
    long_description = f.read()
```

Accordingly, it is highly recommended that you specify the encoding explicitly when opening text files. If you want to use UTF-8, pass `encoding="utf-8"`. To use the current locale encoding, `encoding="locale"` is supported since Python 3.10.

See also

Python UTF-8 Mode
: Python UTF-8 Mode can be used to change the default encoding to UTF-8 from locale-specific encoding.

PEP 686 **[https://peps.python.org/pep-0686/]**
: Python 3.15 will make Python UTF-8 Mode default.

Opt-in EncodingWarning

New in version 3.10: See **PEP 597** [https://peps.python.org/pep-0597/] for more details.

To find where the default locale encoding is used, you can enable the `-X warn_default_encoding` command line option or set the **`PYTHONWARNDEFAULTENCODING`** environment variable, which will emit an **`EncodingWarning`** when the default encoding is used.

If you are providing an API that uses **`open()`** or **`TextIOWrapper`** and passes `encoding=None` as a parameter, you can use **`text_encoding()`** so that callers of the API will emit an **`EncodingWarning`** if they don't pass an `encoding`. However, please consider using UTF-8 by default (i.e. `encoding="utf-8"`) for new APIs.

High-level Module Interface

io.DEFAULT_BUFFER_SIZE

An int containing the default buffer size used by the module's buffered I/O classes. **`open()`** uses the file's blksize (as obtained by **`os.stat()`**) if possible.

io.open(*file*, *mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*, *closefd=True*, *opener=None*)

This is an alias for the builtin **`open()`** function.

This function raises an auditing event `open` with arguments `path`, `mode` and `flags`. The `mode` and `flags` arguments may have been modified or inferred from the original call.

io.open_code(*path*)

Opens the provided file with mode `'rb'`. This function should be used when the intent is to treat the contents as executable code.

`path` should be a **`str`** and an absolute path.

The behavior of this function may be overridden by an earlier call to the **`PyFile_SetOpenCodeHook()`**. However, assuming that `path` is a **`str`** and an absolute path, `open_code(path)` should always behave the same as `open(path, 'rb')`. Overriding the behavior is intended for additional validation or preprocessing of the file.

New in version 3.8.

io.text_encoding(*encoding*, *stacklevel=2*, */*)

This is a helper function for callables that use **`open()`** or **`TextIOWrapper`** and have an `encoding=None` parameter.

This function returns *encoding* if it is not `None`. Otherwise, it returns `"locale"` or `"utf-8"` depending on UTF-8 Mode.

This function emits an **`EncodingWarning`** if **`sys.flags.warn_default_encoding`** is true and *encoding* is `None`. *stacklevel* specifies where the warning is emitted. For example:

```
def read_text(path, encoding=None):
    encoding = io.text_encoding(encoding)  # stackl
    with open(path, encoding) as f:
        return f.read()
```

In this example, an **`EncodingWarning`** is emitted for the caller of `read_text()`.

See Text Encoding for more information.

New in version 3.10.

Changed in version 3.11: **`text_encoding()`** returns “utf-8” when UTF-8 mode is enabled and *encoding* is `None`.

exception io.BlockingIOError

This is a compatibility alias for the builtin

BlockingIOError exception.

exception io.UnsupportedOperation

An exception inheriting **OSError** and **ValueError** that is raised when an unsupported operation is called on a stream.

See also

sys

contains the standard IO streams: **sys.stdin**, **sys.stdout**, and **sys.stderr**.

Class hierarchy

The implementation of I/O streams is organized as a hierarchy of classes. First abstract base classes (ABCs), which are used to specify the various categories of streams, then concrete classes providing the standard stream implementations.

Note

The abstract base classes also provide default implementations of some methods in order to help implementation of concrete stream classes. For example, **BufferedIOBase** provides unoptimized implementations of **readinto()** and **readline()**.

At the top of the I/O hierarchy is the abstract base class **IOBase**. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise **UnsupportedOperation** if they do not support a given operation.

The **RawIOBase** ABC extends **IOBase**. It deals with the reading and writing of bytes to a stream. **FileIO** subclasses **RawIOBase**

to provide an interface to files in the machine's file system.

The **BufferedIOBase** ABC extends **IOBase**. It deals with buffering on a raw binary stream (**RawIOBase**). Its subclasses, **BufferedWriter**, **BufferedReader**, and **BufferedRWPair** buffer raw binary streams that are writable, readable, and both readable and writable, respectively. **BufferedRandom** provides a buffered interface to seekable streams. Another **BufferedIOBase** subclass, **BytesIO**, is a stream of in-memory bytes.

The **TextIOBase** ABC extends **IOBase**. It deals with streams whose bytes represent text, and handles encoding and decoding to and from strings. **TextIOWrapper**, which extends **TextIOBase**, is a buffered text interface to a buffered raw stream (**BufferedIOBase**). Finally, **StringIO** is an in-memory stream for text.

Argument names are not part of the specification, and only the arguments of **open()** are intended to be used as keyword arguments.

The following table summarizes the ABCs provided by the **io** module:

ABC	Inherits	Abstract Methods	Mixin Methods and Properties
IOBase		`close`, `fileno`, `seek`, `tell`, `truncate`	`__enter__`, `__exit__`, `flush`, `isatty`, `__iter__`, `__next__`, `readable`, `readline`, `readlines`, `seekable`, `tell`, `writable`, and `writelines`
RawIOBase	IOBase	`readinto` and `write`	Inherited IOBase methods, `read`, and `readall`
BufferedIOBase	IOBase	`detach`, `read`, `read1`, and `write`	Inherited IOBase methods, `readinto`, and `readinto1`
TextIOBase	IOBase	`detach`, `read`, `readline`, and `write`	Inherited IOBase methods, `encoding`, `errors`, and `newlines`

I/O Base Classes

class io.IOBase

The abstract base class for all I/O classes.

This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read,

written or seeked.

Even though **IOBase** does not declare **read()** or **write()** because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise a **ValueError** (or **UnsupportedOperation**) when operations they do not support are called.

The basic type used for binary data read from or written to a file is **bytes**. Other bytes-like objects are accepted as method arguments too. Text I/O classes work with **str** data.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise **ValueError** in this case.

IOBase (and its subclasses) supports the iterator protocol, meaning that an **IOBase** object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding character strings). See **readline()** below.

IOBase is also a context manager and therefore supports the **with** statement. In this example, *file* is closed after the **with** statement's suite is finished—even if an exception occurs:

```
with open('spam.txt', 'w') as file:
    file.write('Spam and eggs!')
```

IOBase provides these data attributes and methods:

close()

Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a **ValueError**.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an

effect.

closed

`True` if the stream is closed.

fileno()

Return the underlying file descriptor (an integer) of the stream if it exists. An **`OSError`** is raised if the IO object does not use a file descriptor.

flush()

Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

isatty()

Return `True` if the stream is interactive (i.e., connected to a terminal/tty device).

readable()

Return `True` if the stream can be read from. If `False`, **`read()`** will raise **`OSError`**.

readline(*size* = *-1*, */*)

Read and return one line from the stream. If *size* is specified, at most *size* bytes will be read.

The line terminator is always `b'\n'` for binary files; for text files, the *newline* argument to **`open()`** can be used to select the line terminator(s) recognized.

readlines(*hint* = *-1*, */*)

Read and return a list of lines from the stream. *hint* can be specified to control the number of lines read: no more lines will be read if the total size (in bytes/ characters) of all lines so far exceeds *hint*.

hint values of `0` or less, as well as `None`, are treated as

no hint.

Note that it's already possible to iterate on file objects using `for line in file: ...` without calling `file.readlines()`.

seek(*offset*, *whence*=*SEEK_SET*, /)

Change the stream position to the given byte *offset*. *offset* is interpreted relative to the position indicated by *whence*. The default value for *whence* is **`SEEK_SET`**. Values for *whence* are:

- **`SEEK_SET`** or `0` – start of the stream (the default); *offset* should be zero or positive
- **`SEEK_CUR`** or `1` – current stream position; *offset* may be negative
- **`SEEK_END`** or `2` – end of the stream; *offset* is usually negative

Return the new absolute position.

New in version 3.1: The `SEEK_*` constants.

New in version 3.3: Some operating systems could support additional values, like **`os.SEEK_HOLE`** or **`os.SEEK_DATA`**. The valid values for a file could depend on it being open in text or binary mode.

seekable()

Return `True` if the stream supports random access. If `False`, **`seek()`**, **`tell()`** and **`truncate()`** will raise **`OSError`**.

tell()

Return the current stream position.

truncate(*size*=*None*, /)

Resize the stream to the given *size* in bytes (or the current position if *size* is not specified). The current

stream position isn't changed. This resizing can extend or reduce the current file size. In case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled). The new file size is returned.

Changed in version 3.5: Windows will now zero-fill files when extending.

writable()

Return `True` if the stream supports writing. If `False`, **`write()`** and **`truncate()`** will raise **`OSError`**.

writelines(*lines*, */*)

Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

del()

Prepare for object destruction. **`IOBase`** provides a default implementation of this method that calls the instance's **`close()`** method.

class io.RawIOBase

Base class for raw binary streams. It inherits **`IOBase`**.

Raw binary streams typically provide low-level access to an underlying OS device or API, and do not try to encapsulate it in high-level primitives (this functionality is done at a higher-level in buffered binary streams and text streams, described later in this page).

`RawIOBase` provides these methods in addition to those from **`IOBase`**:

read(*size* = *- 1*, */*)

Read up to *size* bytes from the object and return them. As a convenience, if *size* is unspecified or -1, all bytes

until EOF are returned. Otherwise, only one system call is ever made. Fewer than *size* bytes may be returned if the operating system call returns fewer than *size* bytes.

If 0 bytes are returned, and *size* was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, `None` is returned.

The default implementation defers to **`readall()`** and **`readinto()`**.

readall()

Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

readinto(*b*, /)

Read bytes into a pre-allocated, writable bytes-like object *b*, and return the number of bytes read. For example, *b* might be a **`bytearray`**. If the object is in non-blocking mode and no bytes are available, `None` is returned.

write(*b*, /)

Write the given bytes-like object, *b*, to the underlying raw stream, and return the number of bytes written. This can be less than the length of *b* in bytes, depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. `None` is returned if the raw stream is set not to block and no single byte could be readily written to it. The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

class io.BufferedIOBase

Base class for binary streams that support some kind of buffering. It inherits **`IOBase`**.

The main difference with **RawIOBase** is that methods **read()**, **readinto()** and **write()** will try (respectively) to read as much input as requested or to consume all given output, at the expense of making perhaps more than one system call.

In addition, those methods can raise **BlockingIOError** if the underlying raw stream is in non-blocking mode and cannot take or give enough data; unlike their **RawIOBase** counterparts, they will never return `None`.

Besides, the **read()** method does not have a default implementation that defers to **readinto()**.

A typical **BufferedIOBase** implementation should not inherit from a **RawIOBase** implementation, but wrap one, like **BufferedWriter** and **BufferedReader** do.

BufferedIOBase provides or overrides these data attributes and methods in addition to those from **IOBase**:

raw

The underlying raw stream (a **RawIOBase** instance) that **BufferedIOBase** deals with. This is not part of the **BufferedIOBase** API and may not exist on some implementations.

detach()

Separate the underlying raw stream from the buffer and return it.

After the raw stream has been detached, the buffer is in an unusable state.

Some buffers, like **BytesIO**, do not have the concept of a single raw stream to return from this method. They raise **UnsupportedOperation**.

New in version 3.1.

read(*size*=-1, /)

Read and return up to *size* bytes. If the argument is omitted, `None`, or negative, data is read and returned until EOF is reached. An empty **`bytes`** object is returned if the stream is already at EOF.

If the argument is positive, and the underlying raw stream is not interactive, multiple raw reads may be issued to satisfy the byte count (unless EOF is reached first). But for interactive raw streams, at most one raw read will be issued, and a short result does not imply that EOF is imminent.

A **`BlockingIOError`** is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

read1(*size*=-1, /)

Read and return up to *size* bytes, with at most one call to the underlying raw stream's **`read()`** (or **`readinto()`**) method. This can be useful if you are implementing your own buffering on top of a **`BufferedIOBase`** object.

If *size* is `-1` (the default), an arbitrary number of bytes are returned (more than zero unless EOF is reached).

readinto(*b*, /)

Read bytes into a pre-allocated, writable bytes-like object *b* and return the number of bytes read. For example, *b* might be a **`bytearray`**.

Like **`read()`**, multiple reads may be issued to the underlying raw stream, unless the latter is interactive.

A **`BlockingIOError`** is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

readinto1(*b*, */*)

Read bytes into a pre-allocated, writable bytes-like object *b*, using at most one call to the underlying raw stream's `read()` (or `readinto()`) method. Return the number of bytes read.

A `BlockingIOError` is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

New in version 3.5.

write(*b*, */*)

Write the given bytes-like object, *b*, and return the number of bytes written (always equal to the length of *b* in bytes, since if the write fails an `OSError` will be raised). Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.

When in non-blocking mode, a `BlockingIOError` is raised if the data needed to be written to the raw stream but it couldn't accept all the data without blocking.

The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

Raw File I/O

class io.FileIO(*name*, *mode*=*'r'*, *closefd*=*True*, *opener*=*None*)

A raw binary stream representing an OS-level file containing bytes data. It inherits `RawIOBase`.

The *name* can be one of two things:

- a character string or `bytes` object representing the path to the file which will be opened. In this case

closefd must be `True` (the default) otherwise an error will be raised.

- an integer representing the number of an existing OS-level file descriptor to which the resulting **`FileIO`** object will give access. When the FileIO object is closed this fd will be closed as well, unless *closefd* is set to `False`.

The *mode* can be `'r'`, `'w'`, `'x'` or `'a'` for reading (default), writing, exclusive creation or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. **`FileExistsError`** will be raised if it already exists when opened for creating. Opening a file for creating implies writing, so this mode behaves in a similar way to `'w'`. Add a `'+'` to the mode to allow simultaneous reading and writing.

The **`read()`** (when called with a positive argument), **`readinto()`** and **`write()`** methods on this class will only make one system call.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*name*, *flags*). *opener* must return an open file descriptor (passing **`os.open`** as *opener* results in functionality similar to passing `None`).

The newly created file is non-inheritable.

See the **`open()`** built-in function for examples on using the *opener* parameter.

Changed in version 3.3: The *opener* parameter was added. The `'x'` mode was added.

Changed in version 3.4: The file is now non-inheritable.

`FileIO` provides these data attributes in addition to those from **`RawIOBase`** and **`IOBase`**:

mode

The mode as given in the constructor.

name

The file name. This is the file descriptor of the file when no name is given in the constructor.

Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

class io.BytesIO(*initial_bytes*=*b''*)

A binary stream using an in-memory bytes buffer. It inherits **`BufferedIOBase`**. The buffer is discarded when the **`close()`** method is called.

The optional argument *initial_bytes* is a bytes-like object that contains initial data.

`BytesIO` provides or overrides these methods in addition to those from **`BufferedIOBase`** and **`IOBase`**:

getbuffer()

Return a readable and writable view over the contents of the buffer without copying them. Also, mutating the view will transparently update the contents of the buffer:

```
>>> b = io.BytesIO(b"abcdef")
>>> view = b.getbuffer()
>>> view[2:4] = b"56"
>>> b.getvalue()
b'ab56ef'
```

Note

As long as the view exists, the **`BytesIO`** object cannot be resized or closed.

New in version 3.2.

getvalue()

Return **bytes** containing the entire contents of the buffer.

read1(*size* = -1, /)

In **BytesIO**, this is the same as **read()**.

Changed in version 3.7: The *size* argument is now optional.

readinto1(*b*, /)

In **BytesIO**, this is the same as **readinto()**.

New in version 3.5.

class io.BufferedReader(*raw*, *buffer_size* = *DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a readable, non seekable **RawIOBase** raw binary stream. It inherits **BufferedIOBase**.

When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a **BufferedReader** for the given readable *raw* stream and *buffer_size*. If *buffer_size* is omitted, **DEFAULT_BUFFER_SIZE** is used.

BufferedReader provides or overrides these methods in addition to those from **BufferedIOBase** and **IOBase**:

peek(*size* = 0, /)

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned

may be less or more than requested.

read(*size*=-1, /)

Read and return *size* bytes, or if *size* is not given or negative, until EOF or if the read call would block in non-blocking mode.

read1(*size*=-1, /)

Read and return up to *size* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

Changed in version 3.7: The *size* argument is now optional.

class io.BufferedWriter(*raw*, *buffer_size*=*DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a writeable, non seekable **RawIOBase** raw binary stream. It inherits **BufferedIOBase**.

When writing to this object, data is normally placed into an internal buffer. The buffer will be written out to the underlying **RawIOBase** object under various conditions, including:

- when the buffer gets too small for all pending data;
- when **flush()** is called;
- when a **seek()** is requested (for **BufferedRandom** objects);
- when the **BufferedWriter** object is closed or destroyed.

The constructor creates a **BufferedWriter** for the given writeable *raw* stream. If the *buffer_size* is not given, it defaults to **DEFAULT_BUFFER_SIZE**.

BufferedWriter provides or overrides these methods in addition to those from **BufferedIOBase** and **IOBase**:

flush()

Force bytes held in the buffer into the raw stream. A **BlockingIOError** should be raised if the raw stream blocks.

write(*b*, /)

Write the bytes-like object, *b*, and return the number of bytes written. When in non-blocking mode, a **BlockingIOError** is raised if the buffer needs to be written out but the raw stream blocks.

class io.BufferedRandom(*raw*, *buffer_size*=*DEFAULT_BUFFER_SIZE*)

A buffered binary stream providing higher-level access to a seekable **RawIOBase** raw binary stream. It inherits **BufferedReader** and **BufferedWriter**.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer_size* is omitted it defaults to **DEFAULT_BUFFER_SIZE**.

BufferedRandom is capable of anything **BufferedReader** or **BufferedWriter** can do. In addition, **seek()** and **tell()** are guaranteed to be implemented.

class io.BufferedRWPair(*reader*, *writer*, *buffer_size*=*DEFAULT_BUFFER_SIZE*, /)

A buffered binary stream providing higher-level access to two non seekable **RawIOBase** raw binary streams—one readable, the other writeable. It inherits **BufferedIOBase**.

reader and *writer* are **RawIOBase** objects that are readable and writeable respectively. If the *buffer_size* is omitted it defaults to **DEFAULT_BUFFER_SIZE**.

BufferedRWPair implements all of **BufferedIOBase**'s methods except for **detach()**, which raises **UnsupportedOperation**.

Warning

BufferedRWPair does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use **BufferedRandom** instead.

Text I/O

class io.TextIOBase

Base class for text streams. This class provides a character and line based interface to stream I/O. It inherits **IOBase**.

TextIOBase provides or overrides these data attributes and methods in addition to those from **IOBase**:

encoding

The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

errors

The error setting of the decoder or encoder.

newlines

A string, a tuple of strings, or `None`, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

buffer

The underlying binary buffer (a **BufferedIOBase** instance) that **TextIOBase** deals with. This is not part of the **TextIOBase** API and may not exist in some implementations.

detach()

Separate the underlying binary buffer from the

TextIOBase and return it.

After the underlying buffer has been detached, the **TextIOBase** is in an unusable state.

Some **TextIOBase** implementations, like **StringIO**, may not have the concept of an underlying buffer and calling this method will raise **UnsupportedOperation**.

New in version 3.1.

read(*size*=-1, /)

Read and return at most *size* characters from the stream as a single **str**. If *size* is negative or `None`, reads until EOF.

readline(*size*=-1, /)

Read until newline or EOF and return a single `str`. If the stream is already at EOF, an empty string is returned.

If *size* is specified, at most *size* characters will be read.

seek(*offset*, *whence*=*SEEK_SET*, /)

Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is **SEEK_SET**.

- **SEEK_SET** or `0`: seek from the start of the stream (the default); *offset* must either be a number returned by **TextIOBase.tell()**, or zero. Any other *offset* value produces undefined behaviour.
- **SEEK_CUR** or `1`: "seek" to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- **SEEK_END** or `2`: seek to the end of the stream; *offset* must be zero (all other values are

unsupported).

Return the new absolute position as an opaque number.

New in version 3.1: The `SEEK_*` constants.

tell()

Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

write(*s*, /)

Write the string *s* to the stream and return the number of characters written.

class io.TextIOWrapper(*buffer*, *encoding=None*, *errors=None*, *newline=None*, *line_buffering=False*, *write_through=False*)

A buffered text stream providing higher-level access to a **BufferedIOBase** buffered binary stream. It inherits **TextIOBase**.

encoding gives the name of the encoding that the stream will be decoded or encoded with. It defaults to **locale.getencoding()**. `encoding="locale"` can be used to specify the current locale's encoding explicitly. See Text Encoding for more information.

errors is an optional string that specifies how encoding and decoding errors are to be handled. Pass `'strict'` to raise a **ValueError** exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data. `'backslashreplace'` causes malformed data to be replaced by a backslashed escape sequence. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference) or `'namereplace'` (replace with `\N{...}` escape sequences) can be used. Any other error

handling name that has been registered with **`codecs.register_error()`** is also valid.

newline controls how line endings are handled. It can be `None`, `''`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- When reading input from the stream, if *newline* is `None`, universal newlines mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If *newline* is `''`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If *newline* has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is `None`, any `'\n'` characters written are translated to the system default line separator, **`os.linesep`**. If *newline* is `''` or `'\n'`, no translation takes place. If *newline* is any of the other legal values, any `'\n'` characters written are translated to the given string.

If *line_buffering* is `True`, **`flush()`** is implied when a call to write contains a newline character or a carriage return.

If *write_through* is `True`, calls to **`write()`** are guaranteed not to be buffered: any data written on the **`TextIOWrapper`** object is immediately handled to its underlying binary *buffer*.

Changed in version 3.3: The *write_through* argument has been added.

Changed in version 3.3: The default *encoding* is now `locale.getpreferredencoding(False)` instead of `locale.getpreferredencoding()`. Don't change temporary the locale encoding using **`locale.setlocale()`**, use the current locale encoding instead of the user preferred encoding.

Changed in version 3.10: The *encoding* argument now supports

the `"locale"` dummy encoding name.

`TextIOWrapper` provides these data attributes and methods in addition to those from **`TextIOBase`** and **`IOBase`**:

line_buffering
: Whether line buffering is enabled.

write_through
: Whether writes are passed immediately to the underlying binary buffer.

  New in version 3.7.

reconfigure(**[, encoding][, errors][, newline][, line_buffering][, write_through]*)
: Reconfigure this text stream using new settings for *encoding*, *errors*, *newline*, *line_buffering* and *write_through*.

  Parameters not specified keep current settings, except `errors='strict'` is used when *encoding* is specified but *errors* is not specified.

  It is not possible to change the encoding or newline if some data has already been read from the stream. On the other hand, changing encoding after write is possible.

  This method does an implicit stream flush before setting the new parameters.

  New in version 3.7.

  Changed in version 3.11: The method supports `encoding="locale"` option.

class io.StringIO(*initial_value=''*, *newline='\n'*)
: A text stream using an in-memory text buffer. It inherits **`TextIOBase`**.

The text buffer is discarded when the **`close()`** method is called.

The initial value of the buffer can be set by providing *initial_value*. If newline translation is enabled, newlines will be encoded as if by **`write()`**. The stream is positioned at the start of the buffer which emulates opening an existing file in a `w+` mode, making it ready for an immediate write from the beginning or for a write that would overwrite the initial value. To emulate opening a file in an `a+` mode ready for appending, use `f.seek(0, io.SEEK_END)` to reposition the stream at the end of the buffer.

The *newline* argument works like that of **`TextIOWrapper`**, except that when writing output to the stream, if *newline* is `None`, newlines are written as `\n` on all platforms.

`StringIO` provides this method in addition to those from **`TextIOBase`** and **`IOBase`**:

getvalue()

> Return a `str` containing the entire contents of the buffer. Newlines are decoded as if by **`read()`**, although the stream position is not changed.

Example usage:

```
import io

output = io.StringIO()
output.write('First line.\n')
print('Second line.', file=output)

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

class io.IncrementalNewlineDecoder

A helper codec that decodes newlines for universal newlines mode. It inherits **`codecs.IncrementalDecoder`**.

Performance

This section discusses the performance of the provided concrete I/O implementations.

Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O hides any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain depends on the OS and the kind of I/O which is performed. For example, on some modern OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O. The bottom line, however, is that buffered I/O offers predictable performance regardless of the platform and the backing device. Therefore, it is almost always preferable to use buffered I/O rather than unbuffered I/O for binary data.

Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it requires conversions between unicode and binary data using a character codec. This can become noticeable handling huge amounts of text data like large log files. Also, **`TextIOWrapper.tell()`** and **`TextIOWrapper.seek()`** are both quite slow due to the reconstruction algorithm used.

`StringIO`, however, is a native in-memory unicode container and will exhibit similar speed to **`BytesIO`**.

Multi-threading

`FileIO` objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they wrap are thread-

safe too.

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

`TextIOWrapper` objects are not thread-safe.

Reentrancy

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) are not reentrant. While reentrant calls will not happen in normal situations, they can arise from doing I/O in a `signal` handler. If a thread tries to re-enter a buffered object which it is already accessing, a `RuntimeError` is raised. Note this doesn't prohibit a different thread from entering the buffered object.

The above implicitly extends to text files, since the `open()` function will wrap a buffered object inside a `TextIOWrapper`. This includes standard streams and therefore affects the built-in `print()` function as well.

`time` — Time access and conversions

This module provides various time-related functions. For related functionality, see also the `datetime` and `calendar` modules.

Although this module is always available, not all functions are available on all platforms. Most of the functions defined in this module call platform C library functions with the same name. It may sometimes be helpful to consult the platform documentation, because the semantics of these functions varies among platforms.

An explanation of some terminology and conventions is in order.

- The *epoch* is the point where the time starts, the return value of `time.gmtime(0)`. It is January 1, 1970, 00:00:00 (UTC) on all platforms.
- The term *seconds since the epoch* refers to the total number of elapsed seconds since the epoch, typically excluding leap seconds [https://en.wikipedia.org/wiki/Leap_second]. Leap seconds are excluded from this total on all POSIX-compliant platforms.
- The functions in this module may not handle dates and times before the epoch or far in the future. The cut-off point in the future is determined by the C library; for 32-bit systems, it is typically in 2038.
- Function `strptime()` can parse 2-digit years when given `%y` format code. When 2-digit years are parsed, they are converted according to the POSIX and ISO C standards: values 69–99 are mapped to 1969–1999, and values 0–68 are mapped to 2000–2068.

- UTC is Coordinated Universal Time (formerly known as Greenwich Mean Time, or GMT). The acronym UTC is not a mistake but a compromise between English and French.

- DST is Daylight Saving Time, an adjustment of the timezone by (usually) one hour during part of the year. DST rules are magic (determined by local law) and can change from year to year. The C library has a table containing the local rules (often it is read from a system file for flexibility) and is the only source of True Wisdom in this respect.

- The precision of the various real-time functions may be less than suggested by the units in which their value or argument is expressed. E.g. on most Unix systems, the clock "ticks" only 50 or 100 times a second.

- On the other hand, the precision of **`time()`** and **`sleep()`** is better than their Unix equivalents: times are expressed as floating point numbers, **`time()`** returns the most accurate time available (using Unix **`gettimeofday()`** where available), and **`sleep()`** will accept a time with a nonzero fraction (Unix **`select()`** is used to implement this, where available).

- The time value as returned by **`gmtime()`**, **`localtime()`**, and **`strptime()`**, and accepted by **`asctime()`**, **`mktime()`** and **`strftime()`**, is a sequence of 9 integers. The return values of **`gmtime()`**, **`localtime()`**, and **`strptime()`** also offer attribute names for individual fields.

  See **`struct_time`** for a description of these objects.

  Changed in version 3.3: The **`struct_time`** type was extended to provide the **`tm_gmtoff`** and **`tm_zone`** attributes when platform supports corresponding `struct tm` members.

  Changed in version 3.6: The **`struct_time`** attributes **`tm_gmtoff`** and **`tm_zone`** are now available on all platforms.

- Use the following functions to convert between time

representations:

Use	From
[illegible]	seconds since the epoch in UTC
[illegible]	seconds since the epoch in local time
[illegible]	seconds since the epoch in UTC
[illegible]	seconds since the epoch in local time

Functions

time.asctime([*t*])

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a string of the following form: `'Sun Jun 20 23:21:05 1993'`. The day field is two characters long and is space padded if the day is a single digit, e.g.: `'Wed Jun  9 04:26:40 1993'`.

If *t* is not provided, the current time as returned by `localtime()` is used. Locale information is not used by `asctime()`.

Note

Unlike the C function of the same name, `asctime()` does not add a trailing newline.

time.pthread_getcpuclockid(*thread_id*)

Return the *clk_id* of the thread-specific CPU-time clock for the specified *thread_id*.

Use `threading.get_ident()` or the `ident` attribute of `threading.Thread` objects to get a suitable value for *thread_id*.

Warning

Passing an invalid or expired *thread_id* may result in undefined behavior, such as segmentation fault.

Availability: Unix

See the man page for *pthread_getcpuclockid(3)* for further information.

New in version 3.7.

time.clock_getres(*clk_id*)

Return the resolution (precision) of the specified clock *clk_id*. Refer to Clock ID Constants for a list of accepted values for *clk_id*.

Availability: Unix.

New in version 3.3.

time.clock_gettime(*clk_id*) → float

Return the time of the specified clock *clk_id*. Refer to Clock ID Constants for a list of accepted values for *clk_id*.

Use `clock_gettime_ns()` to avoid the precision loss caused by the `float` type.

Availability: Unix.

New in version 3.3.

time.clock_gettime_ns(*clk_id*) → int

Similar to `clock_gettime()` but return time as nanoseconds.

Availability: Unix.

New in version 3.7.

time.clock_settime(*clk_id*, *time: float*)

Set the time of the specified clock *clk_id*. Currently, `CLOCK_REALTIME` is the only accepted value for *clk_id*.

Use **clock_settime_ns()** to avoid the precision loss caused by the **float** type.

Availability: Unix.

New in version 3.3.

time.clock_settime_ns(*clk_id*, *time: int*)

Similar to **clock_settime()** but set time with nanoseconds.

Availability: Unix.

New in version 3.7.

time.ctime([*secs*])

Convert a time expressed in seconds since the epoch to a string of a form: `'Sun Jun 20 23:21:05 1993'` representing local time. The day field is two characters long and is space padded if the day is a single digit, e.g.: `'Wed Jun  9 04:26:40 1993'`.

If *secs* is not provided or **None**, the current time as returned by **time()** is used. `ctime(secs)` is equivalent to `asctime(localtime(secs))`. Locale information is not used by **ctime()**.

time.get_clock_info(*name*)

Get information on the specified clock as a namespace object. Supported clock names and the corresponding functions to read their value are:

- `'monotonic'`: **time.monotonic()**
- `'perf_counter'`: **time.perf_counter()**
- `'process_time'`: **time.process_time()**
- `'thread_time'`: **time.thread_time()**
- `'time'`: **time.time()**

The result has the following attributes:

- *adjustable*: `True` if the clock can be changed automatically (e.g. by a NTP daemon) or manually by the system administrator, `False` otherwise
- *implementation*: The name of the underlying C function used to get the clock value. Refer to Clock ID Constants for possible values.
- *monotonic*: `True` if the clock cannot go backward, `False` otherwise
- *resolution*: The resolution of the clock in seconds (**`float`**)

New in version 3.3.

time.gmtime([*secs*])

Convert a time expressed in seconds since the epoch to a **`struct_time`** in UTC in which the dst flag is always zero. If *secs* is not provided or **`None`**, the current time as returned by **`time()`** is used. Fractions of a second are ignored. See above for a description of the **`struct_time`** object. See **`calendar.timegm()`** for the inverse of this function.

time.localtime([*secs*])

Like **`gmtime()`** but converts to local time. If *secs* is not provided or **`None`**, the current time as returned by **`time()`** is used. The dst flag is set to `1` when DST applies to the given time.

`localtime()` may raise **`OverflowError`**, if the timestamp is outside the range of values supported by the platform C **`localtime()`** or **`gmtime()`** functions, and **`OSError`** on **`localtime()`** or **`gmtime()`** failure. It's common for this to be restricted to years between 1970 and 2038.

time.mktime(*t*)

This is the inverse function of **`localtime()`**. Its argument is the **`struct_time`** or full 9-tuple (since the dst flag is needed; use `-1` as the dst flag if it is unknown) which expresses the time in *local* time, not UTC. It returns a floating

point number, for compatibility with `time()`. If the input value cannot be represented as a valid time, either `OverflowError` or `ValueError` will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

time.monotonic() → float

Return the value (in fractional seconds) of a monotonic clock, i.e. a clock that cannot go backwards. The clock is not affected by system clock updates. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use `monotonic_ns()` to avoid the precision loss caused by the `float` type.

New in version 3.3.

Changed in version 3.5: The function is now always available and always system-wide.

Changed in version 3.10: On macOS, the function is now system-wide.

time.monotonic_ns() → int

Similar to `monotonic()`, but return time as nanoseconds.

New in version 3.7.

time.perf_counter() → float

Return the value (in fractional seconds) of a performance counter, i.e. a clock with the highest available resolution to measure a short duration. It does include time elapsed during sleep and is system-wide. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use `perf_counter_ns()` to avoid the precision loss caused

by the **float** type.

New in version 3.3.

Changed in version 3.10: On Windows, the function is now system-wide.

time.perf_counter_ns() → int

Similar to **perf_counter()**, but return time as nanoseconds.

New in version 3.7.

time.process_time() → float

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current process. It does not include time elapsed during sleep. It is process-wide by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls is valid.

Use **process_time_ns()** to avoid the precision loss caused by the **float** type.

New in version 3.3.

time.process_time_ns() → int

Similar to **process_time()** but return time as nanoseconds.

New in version 3.7.

time.sleep(*secs*)

Suspend execution of the calling thread for the given number of seconds. The argument may be a floating point number to indicate a more precise sleep time.

If the sleep is interrupted by a signal and no exception is raised by the signal handler, the sleep is restarted with a

recomputed timeout.

The suspension time may be longer than requested by an arbitrary amount, because of the scheduling of other activity in the system.

On Windows, if *secs* is zero, the thread relinquishes the remainder of its time slice to any other thread that is ready to run. If there are no other threads ready to run, the function returns immediately, and the thread continues execution. On Windows 8.1 and newer the implementation uses a high-resolution timer [https://docs.microsoft.com/en-us/windows-hardware/drivers/kernel/high-resolution-timers] which provides resolution of 100 nanoseconds. If *secs* is zero, `Sleep(0)` is used.

Unix implementation:

- Use `clock_nanosleep()` if available (resolution: 1 nanosecond);
- Or use `nanosleep()` if available (resolution: 1 nanosecond);
- Or use `select()` (resolution: 1 microsecond).

Changed in version 3.11: On Unix, the `clock_nanosleep()` and `nanosleep()` functions are now used if available. On Windows, a waitable timer is now used.

Changed in version 3.5: The function now sleeps at least *secs* even if the sleep is interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

time.strftime(*format*[, *t*])

Convert a tuple or **`struct_time`** representing a time as returned by **`gmtime()`** or **`localtime()`** to a string as specified by the *format* argument. If *t* is not provided, the current time as returned by **`localtime()`** is used. *format* must be a string. **`ValueError`** is raised if any field in *t* is outside of the allowed range.

0 is a legal argument for any position in the time tuple; if it is

normally illegal the value is forced to a correct one.

The following directives can be embedded in the *format* string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the `strftime()` result:

Directive	Meaning	Notes
%a	Locale's abbreviated weekday name.	
%A	Locale's full weekday name.	
%b	Locale's abbreviated month name.	
%B	Locale's full month name.	
%c	Locale's appropriate date and time representation.	
%d	Day of the month as a decimal number [01,31].	
%H	Hour (24-hour clock) as a decimal number [00,23].	
%I	Hour (12-hour clock) as a decimal number [01,12].	
%j	Day of the year as a decimal number [001,366].	
%m	Month as a decimal number [01,12].	
%M	Minute as a decimal number [00,59].	
%p	Locale's equivalent of either AM or PM.	(1)
%S	Second as a decimal number [00,61].	(2)
%U	Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.	(3)
%w	Weekday as a decimal number [0(Sunday),6].	
%W	Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.	(3)
%x	Locale's appropriate date representation.	
%X	Locale's appropriate time representation.	
%y	Year without century as a decimal number [00,99].	
%Y	Year with century as a decimal number.	
%z	Time zone offset indicating a positive or negative time difference from UTC/GMT of the form +HHMM or -HHMM, where H represents decimal hour digits and M represents decimal minute digits [-23:59, +23:59].	1
%Z	Time zone name (no characters if no time zone exists). Deprecated.	1
%%	A literal `'%'` character.	

Notes:

1. When used with the **`strptime()`** function, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
2. The range really is `0` to `61`; value `60` is valid in timestamps representing leap seconds [https://en.wikipedia.org/wiki/Leap_second] and value `61` is supported for historical reasons.
3. When used with the **`strptime()`** function, `%U` and `%W` are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html] Internet email standard. 1

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime(
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C. To see the full set of format codes supported on your platform, consult the *strftime(3)* documentation.

On some platforms, an optional field width and precision specification can immediately follow the initial `'%'` of a directive in the following order; this is also not portable. The field width is normally 2 except for `%j` where it is 3.

time.strptime(*string*[, *format*])

Parse a string representing a time according to a format. The return value is a **`struct_time`** as returned by **`gmtime()`** or **`localtime()`**.

The *format* parameter uses the same directives as those used by **`strftime()`**; it defaults to `"%a %b %d %H:%M:%S %Y"` which matches the formatting returned by **`ctime()`**. If *string* cannot be parsed according to *format*, or if it has excess data after parsing, **`ValueError`** is raised. The default values used to fill in any missing data when more accurate values

cannot be inferred are `(1900, 1, 1, 0, 0, 0, 0, 1, -1)`. Both *string* and *format* must be strings.

For example:

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=3
                 tm_sec=0, tm_wday=3, tm_yday=335,
```

Support for the `%Z` directive is based on the values contained in `tzname` and whether `daylight` is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because `strftime()` is implemented per platform it can sometimes offer more directives than those listed. But `strptime()` is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

class time.struct_time

The type of the time value sequence returned by **`gmtime()`**, **`localtime()`**, and **`strptime()`**. It is an object with a named tuple interface: values can be accessed by index and by attribute name. The following values are present:

Index	Attribute	Values
0	tm_year	(for example, 1993)
1	tm_mon	range [1, 12]
2	tm_mday	range [1, 31]
3	tm_hour	range [0, 23]
4	tm_min	range [0, 59]
5	tm_sec	range [0, 61]; see **(2)** in **`strftime()`** description
6	tm_wday	range [0, 6], Monday is 0
7	tm_yday	range [1, 366]
8	tm_isdst	0, 1 or -1; see below
N/A	tm_zone	abbreviation of timezone name

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11].

In calls to `mktime()`, `tm_isdst` may be set to 1 when daylight savings time is in effect, and 0 when it is not. A value of -1 indicates that this is not known, and will usually result in the correct state being filled in.

When a tuple with an incorrect length is passed to a function expecting a `struct_time`, or having elements of the wrong type, a `TypeError` is raised.

time.time() → float

Return the time in seconds since the epoch as a floating point number. The handling of leap seconds [https://en.wikipedia.org/wiki/Leap_second] is platform dependent. On Windows and most Unix systems, the leap seconds are not counted towards the time in seconds since the epoch. This is commonly referred to as Unix time [https://en.wikipedia.org/wiki/Unix_time].

Note that even though the time is always returned as a floating point number, not all systems provide time with a better precision than 1 second. While this function normally returns non-decreasing values, it can return a lower value than a previous call if the system clock has been set back between the two calls.

The number returned by `time()` may be converted into a more common time format (i.e. year, month, day, hour, etc…) in UTC by passing it to `gmtime()` function or in local time by passing it to the `localtime()` function. In both cases a `struct_time` object is returned, from which the components of the calendar date may be accessed as attributes.

Use `time_ns()` to avoid the precision loss caused by the `float` type.

time.time_ns() → int

Similar to **time()** but returns time as an integer number of nanoseconds since the epoch.

New in version 3.7.

time.thread_time() → float

Return the value (in fractional seconds) of the sum of the system and user CPU time of the current thread. It does not include time elapsed during sleep. It is thread-specific by definition. The reference point of the returned value is undefined, so that only the difference between the results of two calls in the same thread is valid.

Use **thread_time_ns()** to avoid the precision loss caused by the **float** type.

Availability: Linux, Unix, Windows.

Unix systems supporting `CLOCK_THREAD_CPUTIME_ID`.

New in version 3.7.

time.thread_time_ns() → int

Similar to **thread_time()** but return time as nanoseconds.

New in version 3.7.

time.tzset()

Reset the time conversion rules used by the library routines. The environment variable **TZ** specifies how this is done. It will also set the variables `tzname` (from the **TZ** environment variable), `timezone` (non-DST seconds West of UTC), `altzone` (DST seconds west of UTC) and `daylight` (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present or future when daylight saving time applies).

Availability: Unix.

Note

Although in many cases, changing the **TZ** environment variable may affect the output of functions like **localtime()** without calling **tzset()**, this behavior should not be relied on.

The **TZ** environment variable should contain no whitespace.

The standard format of the **TZ** environment variable is (whitespace added for clarity):

```
std offset [dst [offset [,start[/time], end[/time]]
```

Where the components are:

`std` and `dst`

Three or more alphanumerics giving the timezone abbreviations. These will be propagated into time.tzname

`offset`

The offset has the form: `± hh[:mm[:ss]]`. This indicates the value added the local time to arrive at UTC. If preceded by a '-', the timezone is east of the Prime Meridian; otherwise, it is west. If no offset follows dst, summer time is assumed to be one hour ahead of standard time.

`start[/time], end[/time]`

Indicates when to change to and back from DST. The format of the start and end dates are one of the following:

Jn

The Julian day *n* ($1 <= n <= 365$). Leap days are not counted, so in all years February 28 is

day 59 and March 1 is day 60.

n
: The zero-based Julian day (0 <= *n* <= 365). Leap days are counted, and it is possible to refer to February 29.

M*m*.*n*.*d*
: The *d*'th day (0 <= *d* <= 6) of week *n* of month *m* of the year (1 <= *n* <= 5, 1 <= *m* <= 12, where week 5 means "the last *d* day in month *m*" which may occur in either the fourth or the fifth week). Week 1 is the first week in which the *d*'th day occurs. Day zero is a Sunday.

`time` has the same format as `offset` except that no leading sign ('-' or '+') is allowed. The default, if time is not given, is 02:00:00.

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

On many Unix systems (including *BSD, Linux, Solaris, and Darwin), it is more convenient to use the system's zoneinfo (*tzfile(5)*) database to specify the timezone rules. To do this, set the **`TZ`** environment variable to the path of the required timezone datafile, relative to the root of the systems 'zoneinfo' timezone database, usually located at `/usr/share/zoneinfo`. For example, `'US/Eastern'`, `'Australia/Melbourne'`, `'Egypt'` or `'Europe/Amsterdam'`.

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
```

```
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

Clock ID Constants

These constants are used as parameters for **`clock_getres()`** and **`clock_gettime()`**.

time.CLOCK_BOOTTIME

Identical to **`CLOCK_MONOTONIC`**, except it also includes any time that the system is suspended.

This allows applications to get a suspend-aware monotonic clock without having to deal with the complications of **`CLOCK_REALTIME`**, which may have discontinuities if the time is changed using `settimeofday()` or similar.

Availability: Linux >= 2.6.39.

New in version 3.7.

time.CLOCK_HIGHRES

The Solaris OS has a `CLOCK_HIGHRES` timer that attempts to use an optimal hardware source, and may give close to nanosecond resolution. `CLOCK_HIGHRES` is the nonadjustable, high-resolution clock.

Availability: Solaris.

New in version 3.3.

time.CLOCK_MONOTONIC

Clock that cannot be set and represents monotonic time since some unspecified starting point.

Availability: Unix.

New in version 3.3.

time.CLOCK_MONOTONIC_RAW

Similar to **CLOCK_MONOTONIC**, but provides access to a raw hardware-based time that is not subject to NTP adjustments.

Availability: Linux >= 2.6.28, macOS >= 10.12.

New in version 3.3.

time.CLOCK_PROCESS_CPUTIME_ID

High-resolution per-process timer from the CPU.

Availability: Unix.

New in version 3.3.

time.CLOCK_PROF

High-resolution per-process timer from the CPU.

Availability: FreeBSD, NetBSD >= 7, OpenBSD.

New in version 3.7.

time.CLOCK_TAI

International Atomic Time [https://www.nist.gov/pml/time-and-frequency-division/nist-time-frequently-asked-questions-faq#tai]

The system must have a current leap second table in order for this to give the correct answer. PTP or NTP software can maintain a leap second table.

Availability: Linux.

New in version 3.9.

time.CLOCK_THREAD_CPUTIME_ID

Thread-specific CPU-time clock.

Availability: Unix.

New in version 3.3.

time.CLOCK_UPTIME
: Time whose absolute value is the time the system has been running and not suspended, providing accurate uptime measurement, both absolute and interval.

  Availability: FreeBSD, OpenBSD >= 5.5.

  New in version 3.7.

time.CLOCK_UPTIME_RAW
: Clock that increments monotonically, tracking the time since an arbitrary point, unaffected by frequency or time adjustments and not incremented while the system is asleep.

  Availability: macOS >= 10.12.

  New in version 3.8.

The following constant is the only parameter that can be sent to `clock_settime()`.

time.CLOCK_REALTIME
: System-wide real-time clock. Setting this clock requires appropriate privileges.

  Availability: Unix.

  New in version 3.3.

Timezone Constants

time.altzone
: The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only

use this if `daylight` is nonzero. See note below.

time.daylight
: Nonzero if a DST timezone is defined. See note below.

time.timezone
: The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK). See note below.

time.tzname
: A tuple of two strings: the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used. See note below.

Note

For the above Timezone constants (**`altzone`**, **`daylight`**, **`timezone`**, and **`tzname`**), the value is determined by the timezone rules in effect at module load time or the last time **`tzset()`** is called and may be incorrect for times in the past. It is recommended to use the **`tm_gmtoff`** and **`tm_zone`** results from **`localtime()`** to obtain timezone information.

See also

Module `datetime`
: More object-oriented interface to dates and times.

Module `locale`
: Internationalization services. The locale setting affects the interpretation of many format specifiers in **`strftime()`** and **`strptime()`**.

Module `calendar`
: General calendar-related functions. **`timegm()`** is the inverse of **`gmtime()`** from this module.

Footnotes

1(*1*,*2*,*3*)

The use of `%Z` is now deprecated, but the `%z` escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 **RFC 822** [https://datatracker.ietf.org/doc/html/rfc822.html] standard calls for a two-digit year (`%y` rather than `%Y`), but practice moved to 4-digit years long before the year 2000. After that, **RFC 822** [https://datatracker.ietf.org/doc/html/rfc822.html] became obsolete and the 4-digit year has been first recommended by **RFC 1123** [https://datatracker.ietf.org/doc/html/rfc1123.html] and then mandated by **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html].

`argparse` — Parser for command-line options, arguments and sub-commands

New in version 3.2.

Source code: Lib/argparse.py [https://github.com/python/cpython/tree/3.11/Lib/argparse.py]

Tutorial

This page contains the API reference information. For a more gentle introduction to Python command-line parsing, have a look at the argparse tutorial.

The `argparse` module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and `argparse` will figure out how to parse those out of `sys.argv`. The `argparse` module also automatically generates help and usage messages. The module will also issue errors when users give the program invalid arguments.

Core Functionality

The `argparse` module's support for command-line interfaces is built around an instance of `argparse.ArgumentParser`. It is a container for argument specifications and has options that apply the parser as whole:

```
parser = argparse.ArgumentParser(
                    prog = 'ProgramName',
                    description = 'What the program does
                    epilog = 'Text at the bottom of help
```

The **`ArgumentParser.add_argument()`** method attaches individual argument specifications to the parser. It supports positional arguments, options that accept values, and on/off flags:

```
parser.add_argument('filename')           # positional a
parser.add_argument('-c', '--count')      # option that
parser.add_argument('-v', '--verbose',
                    action='store_true')  # on/off flag
```

The **`ArgumentParser.parse_args()`** method runs the parser and places the extracted data in a **`argparse.Namespace`** object:

```
args = parser.parse_args()
print(args.filename, args.count, args.verbose)
```

Quick Links for add_argument()

Name	Description
`action`	Specify how an argument should be handled
`choices`	Limit values to a specific set of choices
`const`	Store a constant value
`default`	Default value used when an argument is not provided
`dest`	Specify the attribute name used in the result namespace
`help`	Help message for an argument
`metavar`	Alternate display name for the argument as shown in help
`nargs`	Number of times the argument can be used
`required`	Indicate whether an argument is required or optional
`type`	Automatically convert an argument to the given type

Example

The following code is a Python program that takes a list of integers and produces either the sum or the max:

```
import argparse

parser = argparse.ArgumentParser(description='Process so
parser.add_argument('integers', metavar='N', type=int, n
```

```
                    help='an integer for the accumulator
parser.add_argument('--sum', dest='accumulate', action='
                    const=sum, default=max,
                    help='sum the integers (default: fir

args = parser.parse_args()
print(args.accumulate(args.integers))
```

Assuming the above Python code is saved into a file called `prog.py`, it can be run at the command line and it provides useful help messages:

```
$ python prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

Process some integers.

positional arguments:
 N           an integer for the accumulator

options:
 -h, --help  show this help message and exit
 --sum       sum the integers (default: find the max)
```

When run with the appropriate arguments, it prints either the sum or the max of the command-line integers:

```
$ python prog.py 1 2 3 4
4

$ python prog.py 1 2 3 4 --sum
10
```

If invalid arguments are passed in, an error will be displayed:

```
$ python prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'
```

The following sections walk you through this example.

Creating a parser

The first step in using the **argparse** is creating an **ArgumentParser** object:

```
>>> parser = argparse.ArgumentParser(description='Proces
```

The **ArgumentParser** object will hold all the information necessary to parse the command line into Python data types.

Adding arguments

Filling an **ArgumentParser** with information about program arguments is done by making calls to the **add_argument()** method. Generally, these calls tell the **ArgumentParser** how to take the strings on the command line and turn them into objects. This information is stored and used when **parse_args()** is called. For example:

```
>>> parser.add_argument('integers', metavar='N', type=ir
...                     help='an integer for the accumul
>>> parser.add_argument('--sum', dest='accumulate', acti
...                     const=sum, default=max,
...                     help='sum the integers (default:
```

Later, calling **parse_args()** will return an object with two attributes, `integers` and `accumulate`. The `integers` attribute will be a list of one or more integers, and the `accumulate` attribute will be either the **sum()** function, if `--sum` was specified at the command line, or the **max()** function if it was not.

Parsing arguments

ArgumentParser parses arguments through the **parse_args()** method. This will inspect the command line, convert each argument to the appropriate type and then invoke the appropriate action. In most cases, this means a simple **Namespace** object will be built up from attributes parsed out of the command line:

```
>>> parser.parse_args(['--sum', '7', '-1', '42'])
```

```
Namespace(accumulate=<built-in function sum>, integers=[
```

In a script, **`parse_args()`** will typically be called with no arguments, and the **`ArgumentParser`** will automatically determine the command-line arguments from **`sys.argv`**.

ArgumentParser objects

class argparse.ArgumentParser(*prog=None*, *usage=None*, *description=None*, *epilog=None*, *parents=[]*, *formatter_class=argparse.HelpFormatter*, *prefix_chars='-'*, *fromfile_prefix_chars=None*, *argument_default=None*, *conflict_handler='error'*, *add_help=True*, *allow_abbrev=True*, *exit_on_error=True*)

Create a new **`ArgumentParser`** object. All parameters should be passed as keyword arguments. Each parameter has its own more detailed description below, but in short they are:

- prog - The name of the program (default: `os.path.basename(sys.argv[0])`)
- usage - The string describing the program usage (default: generated from arguments added to parser)
- description - Text to display before the argument help (by default, no text)
- epilog - Text to display after the argument help (by default, no text)
- parents - A list of **`ArgumentParser`** objects whose arguments should also be included
- formatter_class - A class for customizing the help output
- prefix_chars - The set of characters that prefix optional arguments (default: ‘-‘)
- fromfile_prefix_chars - The set of characters that prefix files from which additional arguments should be read (default: `None`)
- argument_default - The global default value for arguments (default: `None`)
- conflict_handler - The strategy for resolving conflicting optionals (usually unnecessary)

- add_help - Add a `-h/--help` option to the parser (default: `True`)
- allow_abbrev - Allows long options to be abbreviated if the abbreviation is unambiguous. (default: `True`)
- exit_on_error - Determines whether or not ArgumentParser exits with error info when an error occurs. (default: `True`)

Changed in version 3.5: allow_abbrev parameter was added.

Changed in version 3.8: In previous versions, *allow_abbrev* also disabled grouping of short flags such as `-vv` to mean `-v -v`.

Changed in version 3.9: exit_on_error parameter was added.

The following sections describe how each of these are used.

prog

By default, **`ArgumentParser`** objects use `sys.argv[0]` to determine how to display the name of the program in help messages. This default is almost always desirable because it will make the help messages match how the program was invoked on the command line. For example, consider a file named `myprogram.py` with the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

The help for this program will display `myprogram.py` as the program name (regardless of where the program was invoked from):

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

options:
```

```
 -h, --help  show this help message and exit
 --foo FOO   foo help
$ cd ..
$ python subdir/myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

options:
 -h, --help  show this help message and exit
 --foo FOO   foo help
```

To change this default behavior, another value can be supplied using the `prog=` argument to **`ArgumentParser`**:

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]

options:
 -h, --help  show this help message and exit
```

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]

options:
 -h, --help  show this help message and exit
 --foo FOO   foo of the myprogram program
```

usage

By default, **`ArgumentParser`** calculates the usage message from the arguments it contains:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo he
```

```
>>> parser.add_argument('bar', nargs='+', help='bar help
>>> parser.print_help()
usage: PROG [-h] [--foo [FOO]] bar [bar ...]

positional arguments:
 bar           bar help

options:
 -h, --help    show this help message and exit
 --foo [FOO]   foo help
```

The default message can be overridden with the `usage=` keyword argument:

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage=
>>> parser.add_argument('--foo', nargs='?', help='foo he
>>> parser.add_argument('bar', nargs='+', help='bar help
>>> parser.print_help()
usage: PROG [options]

positional arguments:
 bar           bar help

options:
 -h, --help    show this help message and exit
 --foo [FOO]   foo help
```

The `%(prog)s` format specifier is available to fill in the program name in your usage messages.

description

Most calls to the **`ArgumentParser`** constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments:

```
>>> parser = argparse.ArgumentParser(description='A foo
>>> parser.print_help()
```

```
usage: argparse.py [-h]

A foo that bars

options:
 -h, --help  show this help message and exit
```

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the formatter_class argument.

epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to **`ArgumentParser`**:

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

options:
 -h, --help  show this help message and exit

And that's how you'd foo a bar
```

As with the description argument, the `epilog=` text is by default line-wrapped, but this behavior can be adjusted with the formatter_class argument to **`ArgumentParser`**.

parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to `parents=`

argument to **ArgumentParser** can be used. The `parents=` argument takes a list of **ArgumentParser** objects, collects all the positional and optional actions from them, and adds these actions to the **ArgumentParser** object being constructed:

```
>>> parent_parser = argparse.ArgumentParser(add_help=Fal
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)

>>> bar_parser = argparse.ArgumentParser(parents=[parent
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify `add_help=False`. Otherwise, the **ArgumentParser** will see two `-h/--help` options (one in the parent and one in the child) and raise an error.

Note

You must fully initialize the parsers before passing them via `parents=`. If you change the parent parsers after the child parser, those changes will not be reflected in the child.

formatter_class

ArgumentParser objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are four such classes:

class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter
class argparse.MetavarTypeHelpFormatter

RawDescriptionHelpFormatter and **RawTextHelpFormatter** give more control over how textual descriptions are displayed. By default, **ArgumentParser** objects line-wrap the description and epilog texts in command-line help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...             but that is okay''',
...     epilog='''
...             likewise for this epilog whose whitespac
...         be cleaned up and whose words will be wrappe
...         across a couple lines''')
>>> parser.print_help()
usage: PROG [-h]

this description was indented weird but that is okay

options:
 -h, --help  show this help message and exit

likewise for this epilog whose whitespace will be cleane
will be wrapped across a couple lines
```

Passing **RawDescriptionHelpFormatter** as `formatter_class=` indicates that description and epilog are already correctly formatted and should not be line-wrapped:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpForma
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
...         --------------------------------
...             I have indented it
...             exactly the way
...             I want it
```

```
...         '''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
--------------------------------
   I have indented it
   exactly the way
   I want it

options:
 -h, --help  show this help message and exit
```

RawTextHelpFormatter maintains whitespace for all sorts of help text, including argument descriptions. However, multiple new lines are replaced with one. If you wish to preserve multiple blank lines, add spaces between the newlines.

ArgumentDefaultsHelpFormatter automatically adds information about default values to each of the argument help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFor
>>> parser.add_argument('--foo', type=int, default=42, h
>>> parser.add_argument('bar', nargs='*', default=[1, 2,
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar ...]

positional arguments:
 bar         BAR! (default: [1, 2, 3])

options:
 -h, --help  show this help message and exit
 --foo FOO   FOO! (default: 42)
```

MetavarTypeHelpFormatter uses the name of the type argument for each argument as the display name for its values (rather than using the dest as the regular formatter does):

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.MetavarTypeHelpFormatte
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', type=float)
>>> parser.print_help()
usage: PROG [-h] [--foo int] float

positional arguments:
  float

options:
  -h, --help  show this help message and exit
  --foo int
```

prefix_chars

Most command-line options will use `-` as the prefix, e.g. `-f/--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars=` argument to the ArgumentParser constructor:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars=` argument defaults to `'-'`. Supplying a set of characters that does not include `-` will cause `-f/--foo` options to be disallowed.

fromfile_prefix_chars

Sometimes, when dealing with a particularly long argument list, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the `fromfile_prefix_chars=` argument is given to the

ArgumentParser constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example:

```
>>> with open('args.txt', 'w') as fp:
...     fp.write('-f\nbar')
>>> parser = argparse.ArgumentParser(fromfile_prefix_cha
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

Arguments read from a file must by default be one per line (but see also **convert_arg_line_to_args()**) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

argument_default

Generally, argument defaults are specified either by passing a default to **add_argument()** or by calling the **set_defaults()** methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to **ArgumentParser**. For example, to globally suppress attribute creation on **parse_args()** calls, we supply `argument_default=SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(argument_default=ar
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

allow_abbrev

Normally, when you pass an argument list to the **`parse_args()`** method of an **`ArgumentParser`**, it recognizes abbreviations of long options.

This feature can be disabled by setting `allow_abbrev` to `False`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', allow_
>>> parser.add_argument('--foobar', action='store_true')
>>> parser.add_argument('--foonley', action='store_false
>>> parser.parse_args(['--foon'])
usage: PROG [-h] [--foobar] [--foonley]
PROG: error: unrecognized arguments: --foon
```

New in version 3.5.

conflict_handler

`ArgumentParser` objects do not allow two actions with the same option string. By default, **`ArgumentParser`** objects raise an exception if an attempt is made to create an argument with an option string that is already in use:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo hel
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
 ..
ArgumentError: argument --foo: conflicting option string
```

Sometimes (e.g. when using parents) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value `'resolve'` can be supplied to the `conflict_handler=` argument of **`ArgumentParser`**:

```
>>> parser = argparse.ArgumentParser(prog='PROG', confli
>>> parser.add_argument('-f', '--foo', help='old foo hel
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
```

```
usage: PROG [-h] [-f FOO] [--foo FOO]

options:
 -h, --help  show this help message and exit
 -f FOO      old foo help
 --foo FOO   new foo help
```

Note that **ArgumentParser** objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/--foo` action is retained as the `-f` action, because only the `--foo` option string was overridden.

add_help

By default, ArgumentParser objects add an option which simply displays the parser's help message. For example, consider a file named `myprogram.py` containing the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

If `-h` or `--help` is supplied at the command line, the ArgumentParser help will be printed:

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

options:
 -h, --help  show this help message and exit
 --foo FOO   foo help
```

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing `False` as the `add_help=` argument to **ArgumentParser**:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_he
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
```

```
usage: PROG [--foo FOO]

options:
 --foo FOO  foo help
```

The help option is typically `-h/--help`. The exception to this is if the `prefix_chars=` is specified and does not include `-`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix
>>> parser.print_help()
usage: PROG [+h]

options:
  +h, ++help  show this help message and exit
```

exit_on_error

Normally, when you pass an invalid argument list to the **`parse_args()`** method of an **`ArgumentParser`**, it will exit with error info.

If the user would like to catch errors manually, the feature can be enabled by setting `exit_on_error` to `False`:

```
>>> parser = argparse.ArgumentParser(exit_on_error=False
>>> parser.add_argument('--integers', type=int)
_StoreAction(option_strings=['--integers'], dest='intege
>>> try:
...     parser.parse_args('--integers a'.split())
... except argparse.ArgumentError:
...     print('Catching an argumentError')
...
Catching an argumentError
```

New in version 3.9.

The add_argument() method

ArgumentParser.add_argument(*name or flags...* [, *action*] [, *nargs*] [, *const*] [, *default*] [, *type*] [, *choices*] [, *required*] [, *help*] [, *metavar*] [, *dest*])

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are:

- name or flags - Either a name or a list of option strings, e.g. `foo` or `-f, --foo`.
- action - The basic type of action to be taken when this argument is encountered at the command line.
- nargs - The number of command-line arguments that should be consumed.
- const - A constant value required by some action and nargs selections.
- default - The value produced if the argument is absent from the command line and if it is absent from the namespace object.
- type - The type to which the command-line argument should be converted.
- choices - A container of the allowable values for the argument.
- required - Whether or not the command-line option may be omitted (optionals only).
- help - A brief description of what the argument does.
- metavar - A name for the argument in usage messages.
- dest - The name of the attribute to be added to the object returned by **`parse_args()`**.

The following sections describe how each of these are used.

name or flags

The **`add_argument()`** method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to **`add_argument()`** must therefore be either a series of flags, or a simple argument name.

For example, an optional argument could be created like:

```
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like:

```
>>> parser.add_argument('bar')
```

When **`parse_args()`** is called, optional arguments will be identified by the `-` prefix, and the remaining arguments will be assumed to be positional:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: the following arguments are required: bar
```

action

`ArgumentParser` objects associate command-line arguments with actions. These actions can do just about anything with the command-line arguments associated with them, though most actions simply add an attribute to the object returned by **`parse_args()`**. The `action` keyword argument specifies how the command-line arguments should be handled. The supplied actions are:

- `'store'` - This just stores the argument's value. This is the default action. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo')
  >>> parser.parse_args('--foo 1'.split())
  Namespace(foo='1')
  ```

- `'store_const'` - This stores the value specified by the const keyword argument; note that the const keyword argument defaults to `None`. The `'store_const'` action is most commonly used with optional arguments that specify some sort of flag. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_cons
>>> parser.parse_args(['--foo'])
Namespace(foo=42)
```

- `'store_true'` and `'store_false'` - These are special cases of `'store_const'` used for storing the values `True` and `False` respectively. In addition, they create default values of `False` and `True` respectively. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true
>>> parser.add_argument('--bar', action='store_fals
>>> parser.add_argument('--baz', action='store_fals
>>> parser.parse_args('--foo --bar'.split())
Namespace(foo=True, bar=False, baz=True)
```

- `'append'` - This stores a list, and appends each argument value to the list. It is useful to allow an option to be specified multiple times. If the default value is non-empty, the default elements will be present in the parsed value for the option, with any values from the command line appended after those default values. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])
```

- `'append_const'` - This stores a list, and appends the value specified by the const keyword argument to the list; note that the const keyword argument defaults to `None`. The `'append_const'` action is typically useful when multiple arguments need to store constants to the same list. For

example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', acti
>>> parser.add_argument('--int', dest='types', acti
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<class 'str'>, <class 'int'>])
```

- `'count'` - This counts the number of times a keyword argument occurs. For example, this is useful for increasing verbosity levels:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--verbose', '-v', action='
  >>> parser.parse_args(['-vvv'])
  Namespace(verbose=3)
  ```

  Note, the *default* will be `None` unless explicitly set to *0*.

- `'help'` - This prints a complete help message for all the options in the current parser and then exits. By default a help action is automatically added to the parser. See **`ArgumentParser`** for details of how the output is created.

- `'version'` - This expects a `version=` keyword argument in the **`add_argument()`** call, and prints version information and exits when invoked:

  ```
  >>> import argparse
  >>> parser = argparse.ArgumentParser(prog='PROG')
  >>> parser.add_argument('--version', action='versio
  >>> parser.parse_args(['--version'])
  PROG 2.0
  ```

- `'extend'` - This stores a list, and extends each argument value to the list. Example usage:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument("--foo", action="extend", n
  >>> parser.parse_args(["--foo", "f1", "--foo", "f2"
  Namespace(foo=['f1', 'f2', 'f3', 'f4'])
  ```

New in version 3.8.

You may also specify an arbitrary action by passing an Action subclass or other object that implements the same interface. The `BooleanOptionalAction` is available in `argparse` and adds support for boolean actions such as `--foo` and `--no-foo`:

```
>>> import argparse
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=argparse.Boolean
>>> parser.parse_args(['--no-foo'])
Namespace(foo=False)
```

New in version 3.9.

The recommended way to create a custom action is to extend **`Action`**, overriding the `__call__` method and optionally the `__init__` and `format_usage` methods.

An example of a custom action:

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=N
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super().__init__(option_strings, dest, **kwa
...     def __call__(self, parser, namespace, values, op
...         print('%r %r %r' % (namespace, values, optio
...         setattr(namespace, self.dest, values)
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')
```

For more details, see **`Action`**.

nargs

ArgumentParser objects usually associate a single command-line argument with a single action to be taken. The `nargs` keyword argument associates a different number of command-line arguments with a single action. The supported values are:

- `N` (an integer). `N` arguments from the command line will be gathered together into a list. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', nargs=2)
  >>> parser.add_argument('bar', nargs=1)
  >>> parser.parse_args('c --foo a b'.split())
  Namespace(bar=['c'], foo=['a', 'b'])
  ```

  Note that `nargs=1` produces a list of one item. This is different from the default, in which the item is produced by itself.

- `'?'`. One argument will be consumed from the command line if possible, and produced as a single item. If no command-line argument is present, the value from default will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line argument. In this case the value from const will be produced. Some examples to illustrate this:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', nargs='?', const='
  >>> parser.add_argument('bar', nargs='?', default='
  >>> parser.parse_args(['XX', '--foo', 'YY'])
  Namespace(bar='XX', foo='YY')
  >>> parser.parse_args(['XX', '--foo'])
  Namespace(bar='XX', foo='c')
  >>> parser.parse_args([])
  Namespace(bar='d', foo='d')
  ```

  One of the more common uses of `nargs='?'` is to allow optional input and output files:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=a
...                     default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=
...                     default=sys.stdout)
>>> parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<_io.TextIOWrapper name='input.txt
          outfile=<_io.TextIOWrapper name='output.t
>>> parser.parse_args([])
Namespace(infile=<_io.TextIOWrapper name='<stdin>'
          outfile=<_io.TextIOWrapper name='<stdout>
```

- `'*'`. All command-line arguments present are gathered into a list. Note that it generally doesn't make much sense to have more than one positional argument with `nargs='*'`, but multiple optional arguments with `nargs='*'` is possible. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.spl
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x',
```

- `'+'`. Just like `'*'`, all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn't at least one command-line argument present. For example:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: the following arguments are required:
```

If the `nargs` keyword argument is not provided, the number of arguments consumed is determined by the action. Generally this

means a single command-line argument will be consumed and a single item (not a list) will be produced.

const

The `const` argument of **`add_argument()`** is used to hold constant values that are not read from the command line but are required for the various **`ArgumentParser`** actions. The two most common uses of it are:

- When **`add_argument()`** is called with `action='store_const'` or `action='append_const'`. These actions add the `const` value to one of the attributes of the object returned by **`parse_args()`**. See the action description for examples. If `const` is not provided to **`add_argument()`**, it will receive a default value of `None`.
- When **`add_argument()`** is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line arguments. When parsing the command line, if the option string is encountered with no command-line argument following it, the value of `const` will be assumed to be `None` instead. See the nargs description for examples.

Changed in version 3.11: `const=None` by default, including when `action='append_const'` or `action='store_const'`.

default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of **`add_argument()`**, whose value defaults to `None`, specifies what value should be used if the command-line argument is not present. For optional arguments, the `default` value is used when the option string was not present at the command line:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
Namespace(foo='2')
```

```
>>> parser.parse_args([])
Namespace(foo=42)
```

If the target namespace already has an attribute set, the action *default* will not over write it:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args([], namespace=argparse.Namespace(f
Namespace(foo=101)
```

If the `default` value is a string, the parser parses the value as if it were a command-line argument. In particular, the parser applies any type conversion argument, if provided, before setting the attribute on the **`Namespace`** return value. Otherwise, the parser uses the value as is:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=i
>>> parser.add_argument('--width', default=10.5, type=in
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

For positional arguments with nargs equal to `?` or `*`, the `default` value is used when no command-line argument was present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
>>> parser.parse_args([])
Namespace(foo=42)
```

Providing `default=argparse.SUPPRESS` causes no attribute to be added if the command-line argument was not present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRE
>>> parser.parse_args([])
Namespace()
```

```
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

type

By default, the parser reads command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, such as a **`float`** or **`int`**. The `type` keyword for **`add_argument()`** allows any necessary type-checking and type conversions to be performed.

If the type keyword is used with the default keyword, the type converter is only applied if the default is a string.

The argument to `type` can be any callable that accepts a single string. If the function raises **`ArgumentTypeError`**, **`TypeError`**, or **`ValueError`**, the exception is caught and a nicely formatted error message is displayed. No other exception types are handled.

Common built-in types and functions can be used as type converters:

```
import argparse
import pathlib

parser = argparse.ArgumentParser()
parser.add_argument('count', type=int)
parser.add_argument('distance', type=float)
parser.add_argument('street', type=ascii)
parser.add_argument('code_point', type=ord)
parser.add_argument('source_file', type=open)
parser.add_argument('dest_file', type=argparse.FileType(
parser.add_argument('datapath', type=pathlib.Path)
```

User defined functions can be used as well:

```
>>> def hyphenated(string):
...     return '-'.join([word[:4] for word in string.cas
...
>>> parser = argparse.ArgumentParser()
```

```
>>> _ = parser.add_argument('short_title', type=hyphenat
>>> parser.parse_args(['"The Tale of Two Cities"'])
Namespace(short_title='"the-tale-of-two-citi')
```

The **`bool()`** function is not recommended as a type converter. All it does is convert empty strings to `False` and non-empty strings to `True`. This is usually not what is desired.

In general, the `type` keyword is a convenience that should only be used for simple conversions that can only raise one of the three supported exceptions. Anything with more interesting error-handling or resource management should be done downstream after the arguments are parsed.

For example, JSON or YAML conversions have complex error cases that require better reporting than can be given by the `type` keyword. A **`JSONDecodeError`** would not be well formatted and a **`FileNotFound`** exception would not be handled at all.

Even **`FileType`** has its limitations for use with the `type` keyword. If one argument uses *FileType* and then a subsequent argument fails, an error is reported but the file is not automatically closed. In this case, it would be better to wait until after the parser has run and then use the **`with`**-statement to manage the files.

For type checkers that simply check against a fixed set of values, consider using the choices keyword instead.

choices

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a container object as the *choices* keyword argument to **`add_argument()`**. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values:

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper'
>>> parser.parse_args(['rock'])
Namespace(move='rock')
```

```
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (c
'paper', 'scissors')
```

Note that inclusion in the *choices* container is checked after any type conversions have been performed, so the type of the objects in the *choices* container should match the type specified:

```
>>> parser = argparse.ArgumentParser(prog='doors.py')
>>> parser.add_argument('door', type=int, choices=range(
>>> print(parser.parse_args(['3']))
Namespace(door=3)
>>> parser.parse_args(['4'])
usage: doors.py [-h] {1,2,3}
doors.py: error: argument door: invalid choice: 4 (choos
```

Any container can be passed as the *choices* value, so **`list`** objects, **`set`** objects, and custom containers are all supported.

Use of **`enum.Enum`** is not recommended because it is difficult to control its appearance in usage, help, and error messages.

Formatted choices override the default *metavar* which is normally derived from *dest*. This is usually what you want because the user never sees the *dest* parameter. If this display isn't desirable (perhaps because there are many choices), just specify an explicit metavar.

required

In general, the **`argparse`** module assumes that flags like `-f` and `--bar` indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, `True` can be specified for the `required=` keyword argument to **`add_argument()`**:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
```

```
>>> parser.parse_args([])
usage: [-h] --foo FOO
: error: the following arguments are required: --foo
```

As the example shows, if an option is marked as `required`, **`parse_args()`** will report an error if that option is not present at the command line.

Note

Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

help

The `help` value is a string containing a brief description of the argument. When a user requests help (usually by using `-h` or `--help` at the command line), these `help` descriptions will be displayed with each argument:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
...                     help='foo the bars before frobbl
>>> parser.add_argument('bar', nargs='+',
...                     help='one of the bars to be frob
>>> parser.parse_args(['-h'])
usage: frobble [-h] [--foo] bar [bar ...]

positional arguments:
 bar     one of the bars to be frobbled

options:
 -h, --help  show this help message and exit
 --foo   foo the bars before frobbling
```

The `help` strings can include various format specifiers to avoid repetition of things like the program name or the argument default. The available specifiers include the program name, `%(prog)s` and

most keyword arguments to **add_argument()**, e.g. `%(default)s`, `%(type)s`, etc.:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, defa
...                     help='the bar to %(prog)s (defau
>>> parser.print_help()
usage: frobble [-h] [bar]

positional arguments:
 bar     the bar to frobble (default: 42)

options:
 -h, --help  show this help message and exit
```

As the help string supports %-formatting, if you want a literal `%` to appear in the help string, you must escape it as `%%`.

argparse supports silencing the help entry for certain options, by setting the `help` value to `argparse.SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
usage: frobble [-h]

options:
  -h, --help  show this help message and exit
```

metavar

When **ArgumentParser** generates help messages, it needs some way to refer to each expected argument. By default, ArgumentParser objects use the dest value as the “name” of each object. By default, for positional argument actions, the dest value is used directly, and for optional argument actions, the dest value is uppercased. So, a single positional argument with `dest='bar'` will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line argument will be referred to as `FOO`. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage:  [-h] [--foo FOO] bar

positional arguments:
 bar

options:
 -h, --help  show this help message and exit
 --foo FOO
```

An alternative name can be specified with `metavar`:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage:  [-h] [--foo YYY] XXX

positional arguments:
 XXX

options:
 -h, --help  show this help message and exit
 --foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the **`parse_args()`** object is still determined by the dest value.

Different values of `nargs` may cause the metavar to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar'
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]

options:
 -h, --help     show this help message and exit
 -x X X
 --foo bar baz
```

dest

Most **ArgumentParser** actions add some value as an attribute of the object returned by **parse_args()**. The name of this attribute is determined by the `dest` keyword argument of **add_argument()**. For positional argument actions, `dest` is normally supplied as the first argument to **add_argument()**:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of `dest` is normally inferred from the option strings. **ArgumentParser** generates the value of `dest` by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, `dest` will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
```

```
Namespace(foo_bar='1', x='2')
```

`dest` allows a custom attribute name to be provided:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

Action classes

Action classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the `action` parameter to **`add_argument()`**.

class argparse.Action(*option_strings*, *dest*, *nargs*=*None*, *const*=*None*, *default*=*None*, *type*=*None*, *choices*=*None*, *required*=*False*, *help*=*None*, *metavar*=*None*)

Action objects are used by an ArgumentParser to represent the information needed to parse a single argument from one or more strings from the command line. The Action class must accept the two positional arguments plus any keyword arguments passed to **`ArgumentParser.add_argument()`** except for the `action` itself.

Instances of Action (or return value of any callable to the `action` parameter) should have attributes “dest”, “option_strings”, “default”, “type”, “required”, “help”, etc. defined. The easiest way to ensure these attributes are defined is to call `Action.__init__`.

Action instances should be callable, so subclasses must override the `__call__` method, which should accept four parameters:

- `parser` - The ArgumentParser object which contains this action.
- `namespace` - The **`Namespace`** object that will be returned by **`parse_args()`**. Most actions add an attribute to this

object using **setattr()**.

- values - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the type keyword argument to **add_argument()**.
- option_string - The option string that was used to invoke this action. The option_string argument is optional, and will be absent if the action is associated with a positional argument.

The __call__ method may perform arbitrary actions, but will typically set attributes on the namespace based on dest and values.

Action subclasses can define a format_usage method that takes no argument and return a string which will be used when printing the usage of the program. If such method is not provided, a sensible default will be used.

The parse_args() method

ArgumentParser.parse_args(*args* = *None*, *namespace* = *None*)

Convert argument strings to objects and assign them as attributes of the namespace. Return the populated namespace.

Previous calls to **add_argument()** determine exactly what objects are created and how they are assigned. See the documentation for **add_argument()** for details.

- args - List of strings to parse. The default is taken from **sys.argv**.
- namespace - An object to take the attributes. The default is a new empty **Namespace** object.

Option value syntax

The **parse_args()** method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using = to separate them:

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated:

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single - prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

Invalid arguments

While parsing the command line, **`parse_args()`** checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger
```

Arguments containing `-`

The **`parse_args()`** method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The **`parse_args()`** method is cautious here: positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are posit
```

```
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an optio
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an optio
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are o
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument
```

If you have positional arguments that must begin with - and don't look like negative numbers, you can insert the pseudo-argument `'--'` which tells **`parse_args()`** that everything after that is a positional argument:

```
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

Argument abbreviations (prefix matching)

The **`parse_args()`** method by default allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option):

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args('-bac MMM'.split())
```

```
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args('-bad WOOD'.split())
Namespace(bacon=None, badger='WOOD')
>>> parser.parse_args('-ba BA'.split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger,
```

An error is produced for arguments that could produce more than one options. This feature can be disabled by setting allow_abbrev to `False`.

Beyond `sys.argv`

Sometimes it may be useful to have an ArgumentParser parse arguments other than those of **`sys.argv`**. This can be accomplished by passing a list of strings to **`parse_args()`**. This is useful for testing at the interactive prompt:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=rar
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const'
...     default=max, help='sum the integers (default: fi
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[
```

The Namespace object

class argparse.Namespace

> Simple class used by default by **`parse_args()`** to create an object holding attributes and return it.

This class is deliberately simple, just an **`object`** subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, **`vars()`**:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an **`ArgumentParser`** assign attributes to an already existing object, rather than a new **`Namespace`** object. This can be achieved by specifying the `namespace=` keyword argument:

```
>>> class C:
...     pass
...
>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c
>>> c.foo
'BAR'
```

Other utilities

Sub-commands

ArgumentParser.add_subparsers([*title*][, *description*][, *prog*][, *parser_class*][, *action*][, *option_strings*][, *dest*][, *required*][, *help*][, *metavar*])

> Many programs split up their functionality into a number of sub-commands, for example, the `svn` program can invoke sub-commands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. **`ArgumentParser`** supports the creation of such sub-commands with the **`add_subparsers()`** method. The **`add_subparsers()`** method is normally called with no arguments and returns a special action object. This object has

a single method, **`add_parser()`**, which takes a command name and any **`ArgumentParser`** constructor arguments, and returns an **`ArgumentParser`** object that can be modified as usual.

Description of parameters:

- title - title for the sub-parser group in help output; by default “subcommands” if description is provided, otherwise uses title for positional arguments
- description - description for the sub-parser group in help output, by default `None`
- prog - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- parser_class - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. ArgumentParser)
- action - the basic type of action to be taken when this argument is encountered at the command line
- dest - name of the attribute under which sub-command name will be stored; by default `None` and no value is stored
- required - Whether or not a subcommand must be provided, by default `False` (added in 3.7)
- help - help for sub-parser group in help output, by default `None`
- metavar - string presenting available sub-commands in help; by default it is `None` and presents sub-commands in form {cmd1, cmd2, ..}

Some example usage:

```
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true
>>> subparsers = parser.add_subparsers(help='sub-co
>>>
>>> # create the parser for the "a" command
```

```
>>> parser_a = subparsers.add_parser('a', help='a h
>>> parser_a.add_argument('bar', type=int, help='ba
>>>
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b h
>>> parser_b.add_argument('--baz', choices='XYZ', h
>>>
>>> # parse some argument lists
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)
```

Note that the object returned by **`parse_args()`** will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to **`add_parser()`** as above.)

```
>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...

positional arguments:
  {a,b}   sub-command help
    a     a help
    b     b help

options:
  -h, --help  show this help message and exit
  --foo   foo help
```

```
>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar

positional arguments:
  bar     bar help

options:
  -h, --help  show this help message and exit

>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

options:
  -h, --help     show this help message and exit
  --baz {X,Y,Z}  baz help
```

The **`add_subparsers()`** method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subco
...                                    description=
...                                    help='additi
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage:  [-h] {foo,bar} ...

options:
  -h, --help  show this help message and exit

subcommands:
  valid subcommands

  {foo,bar}   additional help
```

Furthermore, `add_parser` supports an additional `aliases` argument, which allows multiple strings to refer to the same subparser. This example, like `svn`, aliases `co` as a shorthand for `checkout`:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>> checkout = subparsers.add_parser('checkout', al
>>> checkout.add_argument('foo')
>>> parser.parse_args(['co', 'bar'])
Namespace(foo='bar')
```

One particularly effective way of handling sub-commands is to combine the use of the **`add_subparsers()`** method with calls to **`set_defaults()`** so that each subparser knows which Python function it should execute. For example:

```
>>> # sub-command functions
>>> def foo(args):
...     print(args.x * args.y)
...
>>> def bar(args):
...     print('((%s))' % args.z)
...
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')
>>> parser_foo.add_argument('-x', type=int, default
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
```

```
>>> # parse the args and call whatever function was
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))
```

This way, you can let **`parse_args()`** do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the `dest` keyword argument to the **`add_subparsers()`** call will work:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subpar
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
Namespace(subparser_name='2', y='frobble')
```

Changed in version 3.7: New *required* keyword argument.

FileType objects

class argparse.FileType(*mode='r'*, *bufsize=-1*, *encoding=None*, *errors=None*)

The **`FileType`** factory creates objects that can be passed to the type argument of **`ArgumentParser.add_argument()`**. Arguments that have **`FileType`** objects as their type will open command-line arguments as files with the requested modes, buffer sizes, encodings and error handling (see the **`open()`** function for more details):

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--raw', type=argparse.File
>>> parser.add_argument('out', type=argparse.FileTy
>>> parser.parse_args(['--raw', 'raw.dat', 'file.tx
Namespace(out=<_io.TextIOWrapper name='file.txt' mo
```

FileType objects understand the pseudo-argument `'-'` and automatically convert this into `sys.stdin` for readable `FileType` objects and `sys.stdout` for writable `FileType` objects:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.Fil
>>> parser.parse_args(['-'])
Namespace(infile=<_io.TextIOWrapper name='<stdin>'
```

New in version 3.4: The *encodings* and *errors* keyword arguments.

Argument groups

ArgumentParser.add_argument_group(*title=None*, *description=None*)

By default, `ArgumentParser` groups command-line arguments into "positional arguments" and "options" when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the `add_argument_group()` method:

```
>>> parser = argparse.ArgumentParser(prog='PROG', a
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo FOO] bar

group:
  bar    bar help
```

```
  --foo FOO  foo help
```

The **add_argument_group()** method returns an argument group object which has an **add_argument()** method just like a regular **ArgumentParser**. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The **add_argument_group()** method accepts *title* and *description* arguments which can be used to customize this display:

```
>>> parser = argparse.ArgumentParser(prog='PROG', a
>>> group1 = parser.add_argument_group('group1', 'g
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'g
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [--bar BAR] foo

group1:
  group1 description

  foo    foo help

group2:
  group2 description

  --bar BAR  bar help
```

Note that any arguments not in your user-defined groups will end up back in the usual “positional arguments” and “optional arguments” sections.

Changed in version 3.11: Calling **add_argument_group()** on an argument group is deprecated. This feature was never supported and does not always work correctly. The function exists on the API by accident through inheritance and will be removed in the future.

Mutual exclusion

ArgumentParser.add_mutually_exclusive_group(*required=False*)

Create a mutually exclusive group. **argparse** will make sure that only one of the arguments in the mutually exclusive group was present on the command line:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true'
>>> group.add_argument('--bar', action='store_false
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argum
```

The **add_mutually_exclusive_group()** method also accepts a *required* argument, to indicate that at least one of the mutually exclusive arguments is required:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(req
>>> group.add_argument('--foo', action='store_true'
>>> group.add_argument('--bar', action='store_false
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is re
```

Note that currently mutually exclusive argument groups do not support the *title* and *description* arguments of **add_argument_group()**.

Changed in version 3.11: Calling **add_argument_group()** or **add_mutually_exclusive_group()** on a mutually exclusive group is deprecated. These features were never supported and do not always work correctly. The functions exist on the API by accident through inheritance and will be removed in the future.

Parser defaults

ArgumentParser.set_defaults(***kwargs*)

Most of the time, the attributes of the object returned by **parse_args()** will be fully determined by inspecting the command-line arguments and the argument actions. **set_defaults()** allows some additional attributes that are determined without any inspection of the command line to be added:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the **add_subparsers()** method for an example of this type.

ArgumentParser.get_default(*dest*)

Get the default value for a namespace attribute, as set by either **add_argument()** or by **set_defaults()**:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'
```

Printing help

In most typical applications, **`parse_args()`** will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

ArgumentParser.print_usage(*file* = *None*)

Print a brief description of how the **`ArgumentParser`** should be invoked on the command line. If *file* is `None`, **`sys.stdout`** is assumed.

ArgumentParser.print_help(*file* = *None*)

Print a help message, including the program usage and information about the arguments registered with the **`ArgumentParser`**. If *file* is `None`, **`sys.stdout`** is assumed.

There are also variants of these methods that simply return a string instead of printing it:

ArgumentParser.format_usage()

Return a string containing a brief description of how the **`ArgumentParser`** should be invoked on the command line.

ArgumentParser.format_help()

Return a string containing a help message, including the program usage and information about the arguments registered with the **`ArgumentParser`**.

Partial parsing

ArgumentParser.parse_known_args(*args* = *None*, *namespace* = *None*)

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the **`parse_known_args()`** method can be useful. It works much like **`parse_args()`** except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR',
(Namespace(bar='BAR', foo=True), ['--badger', 'spam'])
```

Warning

Prefix matching rules apply to **`parse_known_args()`**. The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

Customizing file parsing

ArgumentParser.convert_arg_line_to_args(*arg_line*)

Arguments that are read from a file (see the *fromfile_prefix_chars* keyword argument to the **`ArgumentParser`** constructor) are read one argument per line. **`convert_arg_line_to_args()`** can be overridden for fancier reading.

This method takes a single argument *arg_line* which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument. The following example demonstrates how to do this:

```
class MyArgumentParser(argparse.ArgumentParser):
    def convert_arg_line_to_args(self, arg_line):
        return arg_line.split()
```

Exiting methods

ArgumentParser.exit(*status=0*, *message=None*)

This method terminates the program, exiting with the specified *status* and, if given, it prints a *message* before that. The user can override this method to handle these steps differently:

```
class ErrorCatchingArgumentParser(argparse.Argument
    def exit(self, status=0, message=None):
        if status:
            raise Exception(f'Exiting because of an
        exit(status)
```

ArgumentParser.error(*message*)

This method prints a usage message including the *message* to the standard error and terminates the program with a status code of 2.

Intermixed parsing

ArgumentParser.parse_intermixed_args(*args* = *None*, *namespace* = *None*)

ArgumentParser.parse_known_intermixed_args(*args* = *None*, *namespace* = *None*)

A number of Unix commands allow the user to intermix optional arguments with positional arguments. The **`parse_intermixed_args()`** and **`parse_known_intermixed_args()`** methods support this parsing style.

These parsers do not support all the argparse features, and will raise exceptions if unsupported features are used. In particular, subparsers, `argparse.REMAINDER`, and mutually exclusive groups that include both optionals and positionals are not supported.

The following example shows the difference between **`parse_known_args()`** and **`parse_intermixed_args()`**: the

former returns `['2', '3']` as unparsed arguments, while the latter collects all the positionals into `rest`.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('cmd')
>>> parser.add_argument('rest', nargs='*', type=int)
>>> parser.parse_known_args('doit 1 --foo bar 2 3'.split
(Namespace(cmd='doit', foo='bar', rest=[1]), ['2', '3'])
>>> parser.parse_intermixed_args('doit 1 --foo bar 2 3'.
Namespace(cmd='doit', foo='bar', rest=[1, 2, 3])
```

`parse_known_intermixed_args()` returns a two item tuple containing the populated namespace and the list of remaining argument strings. **`parse_intermixed_args()`** raises an error if there are any remaining unparsed argument strings.

New in version 3.7.

Upgrading optparse code

Originally, the **`argparse`** module had attempted to maintain compatibility with **`optparse`**. However, **`optparse`** was difficult to extend transparently, particularly with the changes required to support the new `nargs=` specifiers and better usage messages. When most everything in **`optparse`** had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

The **`argparse`** module improves on the standard library **`optparse`** module in a number of ways including:

- Handling positional arguments.
- Supporting sub-commands.
- Allowing alternative option prefixes like `+` and `/`.
- Handling zero-or-more and one-or-more style arguments.
- Producing more informative usage messages.
- Providing a much simpler interface for custom `type` and `action`.

A partial upgrade path from **`optparse`** to **`argparse`**:

- Replace all **`optparse.OptionParser.add_option()`** calls with **`ArgumentParser.add_argument()`** calls.
- Replace `(options, args) = parser.parse_args()` with `args = parser.parse_args()` and add additional **`ArgumentParser.add_argument()`** calls for the positional arguments. Keep in mind that what was previously called `options`, now in the **`argparse`** context is called `args`.
- Replace **`optparse.OptionParser.disable_interspersed_args()`** by using **`parse_intermixed_args()`** instead of **`parse_args()`**.
- Replace callback actions and the `callback_*` keyword arguments with `type` or `action` arguments.
- Replace string names for `type` keyword arguments with the corresponding type objects (e.g. int, float, complex, etc).
- Replace **`optparse.Values`** with **`Namespace`** and **`optparse.OptionError`** and **`optparse.OptionValueError`** with **`ArgumentError`**.
- Replace strings with implicit arguments such as `%default` or `%prog` with the standard Python syntax to use dictionaries to format strings, that is, `%(default)s` and `%(prog)s`.
- Replace the OptionParser constructor `version` argument with a call to `parser.add_argument('--version', action='version', version='<the version>')`.

`getopt` — C-style parser for command line options

Source code: Lib/getopt.py [https://github.com/python/cpython/tree/3.11/Lib/getopt.py]

Note

The `getopt` module is a parser for command line options whose API is designed to be familiar to users of the C `getopt()` function. Users who are unfamiliar with the C `getopt()` function or who would like to write less code and get better help and error messages should consider using the `argparse` module instead.

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form '-' and '--'). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception:

getopt.getopt(*args*, *shortopts*, *longopts = []*)

Parses command line options and parameter list. *args* is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. *shortopts* is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (`':'`; i.e., the same format that Unix `getopt()` uses).

Note

Unlike GNU **getopt()**, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

longopts, if specified, must be a list of strings with the names of the long options which should be supported. The leading `'--'` characters should not be included in the option name. Long options which require an argument should be followed by an equal sign (`'='`). Optional arguments are not supported. To accept only long options, *shortopts* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *longopts* is `['foo', 'frob']`, the option `--fo` will match as `--foo`, but `--f` will not match uniquely, so **GetoptError** will be raised.

The return value consists of two elements: the first is a list of `(option, value)` pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., `'-x'`) or two hyphens for long options (e.g., `'--long-option'`), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

getopt.gnu_getopt(*args*, *shortopts*, *longopts* = *[]*)

This function works like **getopt()**, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The **getopt()** function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is `'+'`, or if the environment variable **POSIXLY_CORRECT** is set, then option processing stops as soon as a non-option argument is

encountered.

exception getopt.GetoptError

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes **msg** and **opt** give the error message and related option; if there is no specific option to which the exception relates, **opt** is an empty string.

exception getopt.error

Alias for **GetoptError**; for backward compatibility.

An example using only Unix style options:

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```
>>> s = '--condition=foo --testing --output-file abc.def
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.d
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-f
>>> args
```

```
['a1', 'a2']
```

In a script, typical usage is something like this:

```
import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v",
    except getopt.GetoptError as err:
        # print help information and exit:
        print(err)  # will print something like "option
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
            output = a
        else:
            assert False, "unhandled option"
    # ...

if __name__ == "__main__":
    main()
```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the **argparse** module:

```
import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
```

```
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='st
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..
```

: Alternative command line option and argument parsing library.

`logging` — Logging facility for Python

Source code: Lib/logging/__init__.py [https://github.com/python/cpython/tree/3.11/Lib/logging/__init__.py]

Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

This module defines functions and classes which implement a flexible event logging system for applications and libraries.

The key benefit of having the logging API provided by a standard library module is that all Python modules can participate in logging, so your application log can include your own messages integrated with messages from third-party modules.

The simplest example:

```
>>> import logging
>>> logging.warning('Watch out!')
WARNING:root:Watch out!
```

The module provides a lot of functionality and flexibility. If you are unfamiliar with logging, the best way to get to grips with it is to view the tutorials (**see the links above and on the right**).

The basic classes defined by the module, together with their functions, are listed below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.

Logger Objects

Loggers have the following attributes and methods. Note that Loggers should *NEVER* be instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to **`getLogger()`** with the same name will always return a reference to the same Logger object.

The `name` is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

class logging.Logger

propagate

If this attribute evaluates to true, events logged to this logger will be passed to the handlers of higher level (ancestor) loggers, in addition to any handlers attached to this logger. Messages are passed directly to the ancestor loggers' handlers - neither the level nor filters of the ancestor loggers in question are considered.

If this evaluates to false, logging messages are not

passed to the handlers of ancestor loggers.

Spelling it out with an example: If the propagate attribute of the logger named `A.B.C` evaluates to true, any event logged to `A.B.C` via a method call such as `logging.getLogger('A.B.C').error(...)` will [subject to passing that logger's level and filter settings] be passed in turn to any handlers attached to loggers named `A.B`, `A` and the root logger, after first being passed to any handlers attached to `A.B.C`. If any logger in the chain `A.B.C`, `A.B`, `A` has its `propagate` attribute set to false, then that is the last logger whose handlers are offered the event to handle, and propagation stops at that point.

The constructor sets this attribute to `True`.

Note

If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their propagate setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

setLevel(*level*)

Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored; logging messages which have severity *level* or higher will be emitted by whichever handler or handlers service this logger, unless a handler's level has been set to a higher severity level than *level*.

When a logger is created, the level is set to **`NOTSET`**

(which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level **WARNING**.

The term 'delegation to the parent' means that if a logger has a level of NOTSET, its chain of ancestor loggers is traversed until either an ancestor with a level other than NOTSET is found, or the root is reached.

If an ancestor is found with a level other than NOTSET, then that ancestor's level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of NOTSET, then all messages will be processed. Otherwise, the root's level will be used as the effective level.

See Logging Levels for a list of levels.

Changed in version 3.2: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as **INFO**. Note, however, that levels are internally stored as integers, and methods such as e.g. **getEffectiveLevel()** and **isEnabledFor()** will return/expect to be passed integers.

isEnabledFor(*level*)

Indicates if a message of severity *level* would be processed by this logger. This method checks first the module-level level set by `logging.disable(level)` and then the logger's effective level as determined by **getEffectiveLevel()**.

getEffectiveLevel()

Indicates the effective level for this logger. If a value other than **NOTSET** has been set using **setLevel()**, it is returned. Otherwise, the hierarchy is traversed

towards the root until a value other than **NOTSET** is found, and that value is returned. The value returned is an integer, typically one of **logging.DEBUG**, **logging.INFO** etc.

getChild(*suffix*)

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

New in version 3.2.

debug(*msg*, **args*, ***kwargs*)

Logs a message with level **DEBUG** on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.) No % formatting operation is performed on *msg* when no *args* are supplied.

There are four keyword arguments in *kwargs* which are inspected: *exc_info*, *stack_info*, *stacklevel* and *extra*.

If *exc_info* does not evaluate as false, it causes exception information to be added to the logging message. If an exception tuple (in the format returned by **sys.exc_info()**) or an exception instance is provided, it is used; otherwise, **sys.exc_info()** is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual

logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *stacklevel*, which defaults to `1`. If greater than 1, the corresponding number of stack frames are skipped when computing the line number and function name set in the **`LogRecord`** created for the logging event. This can be used in logging helpers so that the function name, filename and line number recorded are not the information for the helper function/method, but rather its caller. The name of this parameter mirrors the equivalent one in the **`warnings`** module.

The fourth keyword argument is *extra* which can be used to pass a dictionary which is used to populate the _dict_ of the **`LogRecord`** created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fblogg
```

```
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connect
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs  Pr
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the section on LogRecord attributes for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the **`Formatter`** has been set up with a format string which expects 'clientip' and 'user' in the attribute dictionary of the **`LogRecord`**. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized **`Formatter`**s would be used with particular **`Handler`**s.

If no handler is attached to this logger (or any of its ancestors, taking into account the relevant **`Logger.propagate`** attributes), the message will be sent to the handler set on **`lastResort`**.

Changed in version 3.2: The *stack_info* parameter was added.

Changed in version 3.5: The *exc_info* parameter can now

accept exception instances.

Changed in version 3.8: The *stacklevel* parameter was added.

info(*msg*, **args*, ***kwargs*)

Logs a message with level **INFO** on this logger. The arguments are interpreted as for **debug()**.

warning(*msg*, **args*, ***kwargs*)

Logs a message with level **WARNING** on this logger. The arguments are interpreted as for **debug()**.

Note

There is an obsolete method `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

error(*msg*, **args*, ***kwargs*)

Logs a message with level **ERROR** on this logger. The arguments are interpreted as for **debug()**.

critical(*msg*, **args*, ***kwargs*)

Logs a message with level **CRITICAL** on this logger. The arguments are interpreted as for **debug()**.

log(*level*, *msg*, **args*, ***kwargs*)

Logs a message with integer level *level* on this logger. The other arguments are interpreted as for **debug()**.

exception(*msg*, **args*, ***kwargs*)

Logs a message with level **ERROR** on this logger. The arguments are interpreted as for **debug()**. Exception info is added to the logging message. This method

should only be called from an exception handler.

addFilter(*filter*)

Adds the specified filter *filter* to this logger.

removeFilter(*filter*)

Removes the specified filter *filter* from this logger.

filter(*record*)

Apply this logger's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

addHandler(*hdlr*)

Adds the specified handler *hdlr* to this logger.

removeHandler(*hdlr*)

Removes the specified handler *hdlr* from this logger.

findCaller(*stack_info*=*False*, *stacklevel*=*1*)

Finds the caller's source filename and line number. Returns the filename, line number, function name and stack information as a 4-element tuple. The stack information is returned as `None` unless *stack_info* is `True`.

The *stacklevel* parameter is passed from code calling the **`debug()`** and other APIs. If greater than 1, the excess is used to skip stack frames before determining the values to be returned. This will generally be useful when calling logging APIs from helper/wrapper code, so that the information in the event log refers not to the helper/wrapper code, but to the code that calls it.

handle(*record*)

Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using `filter()`.

makeRecord(*name*, *level*, *fn*, *lno*, *msg*, *args*, *exc_info*, *func*=*None*, *extra*=*None*, *sinfo*=*None*)

This is a factory method which can be overridden in subclasses to create specialized `LogRecord` instances.

hasHandlers()

Checks to see if this logger has any handlers configured. This is done by looking for handlers in this logger and its parents in the logger hierarchy. Returns `True` if a handler was found, else `False`. The method stops searching up the hierarchy whenever a logger with the 'propagate' attribute set to false is found - that will be the last logger which is checked for the existence of handlers.

New in version 3.2.

Changed in version 3.7: Loggers can now be pickled and unpickled.

Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

Level	Numeric value
`CRITICAL`	50

40	ERROR
30	WARNING
20	INFO
10	DEBUG
0	NOTSET

Handler Objects

Handlers have the following attributes and methods. Note that **Handler** is never instantiated directly; this class acts as a base for more useful subclasses. However, the **__init__()** method in subclasses needs to call **Handler.__init__()**.

class logging.Handler

init(*level*=*NOTSET*)

Initializes the **Handler** instance by setting its level, setting the list of filters to the empty list and creating a lock (using **createLock()**) for serializing access to an I/O mechanism.

createLock()

Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

acquire()

Acquires the thread lock created with **createLock()**.

release()

Releases the thread lock acquired with **acquire()**.

setLevel(*level*)

Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to **NOTSET** (which causes all messages to be processed).

See Logging Levels for a list of levels.

Changed in version 3.2: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as **INFO**.

setFormatter(*fmt*)

Sets the **Formatter** for this handler to *fmt*.

addFilter(*filter*)

Adds the specified filter *filter* to this handler.

removeFilter(*filter*)

Removes the specified filter *filter* from this handler.

filter(*record*)

Apply this handler's filters to the record and return `True` if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

flush()

Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

close()

Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when **shutdown()** is called. Subclasses should ensure that this gets called from overridden **close()** methods.

handle(*record*)

Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

handleError(*record*)

This method should be called from handlers when an exception is encountered during an **`emit()`** call. If the module-level attribute `raiseExceptions` is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred. (The default value of `raiseExceptions` is `True`, as that is more useful during development).

format(*record*)

Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

emit(*record*)

Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a **`NotImplementedError`**.

Warning

This method is called after a handler-level lock is acquired, which is released after this method returns. When you override this method, note that you should be careful when calling anything that invokes other parts of the logging API which might do locking, because that might result in a deadlock. Specifically:

- Logging configuration APIs acquire the module-level lock, and then individual handler-level locks as those handlers are configured.
- Many logging APIs lock the module-level lock. If such an API is called from this method, it could cause a deadlock if a configuration call is made on another thread, because that thread will try to acquire the module-level lock *before* the handler-level lock, whereas this thread tries to acquire the module-level lock *after* the handler-level lock (because in this method, the handler-level lock has already been acquired).

For a list of handlers included as standard, see **`logging.handlers`**.

Formatter Objects

`Formatter` objects have the following attributes and methods. They are responsible for converting a **`LogRecord`** to (usually) a string which can be interpreted by either a human or an external system. The base **`Formatter`** allows a formatting string to be specified. If none is supplied, the default value of `'%(message)s'` is used, which just includes the message in the logging call. To have additional items of information in the formatted output (such as a timestamp), keep reading.

A Formatter can be initialized with a format string which makes use of knowledge of the **`LogRecord`** attributes - such as the default value mentioned above making use of the fact that the user's message and arguments are pre-formatted into a **`LogRecord`**'s *message* attribute. This format string contains standard Python %-style mapping keys. See section printf-style String Formatting for more information on string formatting.

The useful mapping keys in a **`LogRecord`** are given in the section

on LogRecord attributes.

class logging.Formatter(*fmt=None*, *datefmt=None*, *style='%'*, *validate=True*, ***, *defaults=None*)

Returns a new instance of the **`Formatter`** class. The instance is initialized with a format string for the message as a whole, as well as a format string for the date/time portion of a message. If no *fmt* is specified, `'%(message)s'` is used. If no *datefmt* is specified, a format is used which is described in the **`formatTime()`** documentation.

The *style* parameter can be one of '%', '{' or '$' and determines how the format string will be merged with its data: using one of %-formatting, **`str.format()`** or **`string.Template`**. This only applies to the format string *fmt* (e.g. `'%(message)s'` or `{message}`), not to the actual log messages passed to `Logger.debug` etc; see Using particular formatting styles throughout your application for more information on using {- and $-formatting for log messages.

The *defaults* parameter can be a dictionary with default values to use in custom fields. For example:
`logging.Formatter('%(ip)s %(message)s', defaults={"ip": None})`

Changed in version 3.2: The *style* parameter was added.

Changed in version 3.8: The *validate* parameter was added. Incorrect or mismatched style and fmt will raise a `ValueError`. For example:
`logging.Formatter('%(asctime)s - %(message)s', style='{').`

Changed in version 3.10: The *defaults* parameter was added.

format(*record*)

The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of

preparatory steps are carried out. The *message* attribute of the record is computed using *msg* % *args*. If the formatting string contains `'(asctime)'`, **`formatTime()`** is called to format the event time. If there is exception information, it is formatted using **`formatException()`** and appended to the message. Note that the formatted exception information is cached in attribute *exc_text*. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one **`Formatter`** subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value (by setting the *exc_text* attribute to `None`) after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value, but recalculates it afresh.

If stack information is available, it's appended after the exception information, using **`formatStack()`** to transform it if necessary.

formatTime(*record*, *datefmt*=*None*)

This method should be called from **`format()`** by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows: if *datefmt* (a string) is specified, it is used with **`time.strftime()`** to format the creation time of the record. Otherwise, the format '%Y-%m-%d %H:%M:%S,uuu' is used, where the uuu part is a millisecond value and the other letters are as per the **`time.strftime()`** documentation. An example time in this format is `2003-01-23 00:29:50,411`. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, **`time.localtime()`** is used; to change this for a particular formatter instance, set the `converter`

attribute to a function with the same signature as **`time.localtime()`** or **`time.gmtime()`**. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the `converter` attribute in the `Formatter` class.

Changed in version 3.3: Previously, the default format was hard-coded as in this example: `2010-09-06 22:38:15,292` where the part before the comma is handled by a strptime format string (`'%Y-%m-%d %H:%M:%S'`), and the part after the comma is a millisecond value. Because strptime does not have a format placeholder for milliseconds, the millisecond value is appended using another format string, `'%s,%03d'` — and both of these format strings have been hardcoded into this method. With the change, these strings are defined as class-level attributes which can be overridden at the instance level when desired. The names of the attributes are `default_time_format` (for the strptime format string) and `default_msec_format` (for appending the millisecond value).

Changed in version 3.9: The `default_msec_format` can be `None`.

formatException(*exc_info*)

Formats the specified exception information (a standard exception tuple as returned by **`sys.exc_info()`**) as a string. This default implementation just uses **`traceback.print_exception()`**. The resulting string is returned.

formatStack(*stack_info*)

Formats the specified stack information (a string as returned by **`traceback.print_stack()`**, but with the last newline removed) as a string. This default implementation just returns the input value.

class logging.BufferingFormatter(*linefmt=None*)

A base formatter class suitable for subclassing when you want to format a number of records. You can pass a **`Formatter`** instance which you want to use to format each line (that corresponds to a single record). If not specified, the default formatter (which just outputs the event message) is used as the line formatter.

formatHeader(*records*)

Return a header for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records, a title or a separator line.

formatFooter(*records*)

Return a footer for a list of *records*. The base implementation just returns the empty string. You will need to override this method if you want specific behaviour, e.g. to show the count of records or a separator line.

format(*records*)

Return formatted text for a list of *records*. The base implementation just returns the empty string if there are no records; otherwise, it returns the concatenation of the header, each record formatted with the line formatter, and the footer.

Filter Objects

`Filters` can be used by `Handlers` and `Loggers` for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with 'A.B' will allow events logged by loggers 'A.B', 'A.B.C', 'A.B.C.D', 'A.B.D' etc. but not 'A.BB', 'B.A.B' etc. If initialized with the empty string, all

events are passed.

class logging.Filter(*name*='')

Returns an instance of the **Filter** class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

filter(*record*)

Is the specified record to be logged? Returns zero for no, nonzero for yes. If deemed appropriate, the record may be modified in-place by this method.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using **debug()**, **info()**, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass `Filter`: you can pass any instance which has a `filter` method with the same semantics.

Changed in version 3.2: You don't need to create specialized `Filter` classes, or use other classes with a `filter` method: you can use a function (or other callable) as a filter. The filtering logic will check to see if the filter object has a `filter` attribute: if it does, it's assumed to be a `Filter` and its **filter()** method is called. Otherwise, it's assumed to be a callable and called with the record as the single parameter. The returned value should conform to that returned by **filter()**.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the **LogRecord** being processed. Obviously changing the LogRecord needs to be done

with some care, but it does allow the injection of contextual information into logs (see Using Filters to impart contextual information).

LogRecord Objects

LogRecord instances are created automatically by the **Logger** every time something is logged, and can be created manually via **makeLogRecord()** (for example, from a pickled event received over the wire).

class logging.LogRecord(*name*, *level*, *pathname*, *lineno*, *msg*, *args*, *exc_info*, *func=None*, *sinfo=None*)

Contains all the information pertinent to the event being logged.

The primary information is passed in *msg* and *args*, which are combined using `msg % args` to create the **message** attribute of the record.

Parameters

- **name** (*str*) – The name of the logger used to log the event represented by this **LogRecord**. Note that the logger name in the **LogRecord** will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.
- **level** (*int*) – The numeric level of the logging event (such as `10` for `DEBUG`, `20` for `INFO`, etc). Note that this is converted to *two* attributes of the LogRecord: **levelno** for the numeric value and **levelname** for the corresponding level name.
- **pathname** (*str*) – The full string path of the source file where the logging call was made.
- **lineno** (*int*) – The line number in the

source file where the logging call was made.

- **msg** (*str*) – The event description message, which can be a %-format string with placeholders for variable data.
- **args** (*tuple* | *dict[str, Any]*) – Variable data to merge into the *msg* argument to obtain the event description.
- **exc_info** (*tuple[type[BaseException], BaseException, types.TracebackType]* | *None*) – An exception tuple with the current exception information, as returned by **sys.exc_info()**, or `None` if no exception information is available.
- **func** (*str* | *None*) – The name of the function or method from which the logging call was invoked.
- **sinfo** (*str* | *None*) – A text string representing stack information from the base of the stack in the current thread, up to the logging call.

getMessage()

Returns the message for this **LogRecord** instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, **str()** is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

Changed in version 3.2: The creation of a **LogRecord** has been made more configurable by providing a factory which is used to create the record. The factory can be set using **getLogRecordFactory()** and **setLogRecordFactory()** (see this for the factory's signature).

This functionality can be used to inject your own values into a **`LogRecord`** at creation time. You can use the following pattern:

```
old_factory = logging.getLogRecordFactory()

def record_factory(*args, **kwargs):
    record = old_factory(*args, **kwargs)
    record.custom_attribute = 0xdecafbad
    return record

logging.setLogRecordFactory(record_factory)
```

With this pattern, multiple factories could be chained, and as long as they don't overwrite each other's attributes or unintentionally overwrite the standard attributes listed above, there should be no surprises.

LogRecord attributes

The LogRecord has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the LogRecord constructor parameters and the LogRecord attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

If you are using {}-formatting (**`str.format()`**), you can use `{attrname}` as the placeholder in the format string. If you are using $-formatting (**`string.Template`**), use the form `${attrname}`. In both cases, of course, replace `attrname` with the actual attribute name you want to use.

In the case of {}-formatting, you can specify formatting flags by placing them after the attribute name, separated from it with a colon. For example: a placeholder of `{msecs:03d}` would format a millisecond value of `4` as `004`. Refer to the **`str.format()`** documentation for full details on the options available to you.

Attribute name	Description
args	The tuple of arguments merged into msg to produce message, or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary).
asctime	Human-readable time when the LogRecord was created. By default this is of the form '2003-07-08 16:49:45,896' (the numbers after the comma are millisecond portion of the time).
created	Time when the LogRecord was created (as returned by time.time()).
exc_info	Exception tuple (à la sys.exc_info) or, if no exception has occurred, None.
filename	Filename portion of pathname.
funcName	Name of function containing the logging call.
levelname	Text logging level for the message ('DEBUG', 'INFO', 'WARNING', 'ERROR', 'CRITICAL').
levelno	Numeric logging level for the message (DEBUG, INFO, WARNING, ERROR, CRITICAL).
lineno	Source line number where the logging call was issued (if available).
message	The logged message, computed as msg % args. This is set when Formatter.format() is invoked.
module	Module (name portion of filename).
msecs	Millisecond portion of the time when the LogRecord was created.
msg	The format string passed in the original logging call. Merged with args to produce message, or an arbitrary object (see Using arbitrary objects as messages).
name	Name of the logger used to log the call.
pathname	Full pathname of the source file where the logging call was issued (if available).
process	Process ID (if available).
processName	Process name (if available).
relativeCreated	Time in milliseconds when the LogRecord was created, relative to the time the logging module was loaded.
stack_info	Stack frame information (where available) from the bottom of the stack in the current thread, up to and including the stack frame of the logging call which resulted in the creation of this record.
thread	Thread ID (if available).
threadName	Thread name (if available).

Changed in version 3.1: processName was added.

LoggerAdapter Objects

`LoggerAdapter` instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

class logging.LoggerAdapter(*logger*, *extra*)

Returns an instance of **`LoggerAdapter`** initialized with an underlying **`Logger`** instance and a dict-like object.

process(*msg*, *kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key 'extra'. The return value is a (*msg*, *kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

In addition to the above, **`LoggerAdapter`** supports the following methods of **`Logger`**: **`debug()`**, **`info()`**, **`warning()`**, **`error()`**, **`exception()`**, **`critical()`**, **`log()`**, **`isEnabledFor()`**, **`getEffectiveLevel()`**, **`setLevel()`** and **`hasHandlers()`**. These methods have the same signatures as their counterparts in **`Logger`**, so you can use the two types of instances interchangeably.

Changed in version 3.2: The **`isEnabledFor()`**, **`getEffectiveLevel()`**, **`setLevel()`** and **`hasHandlers()`** methods were added to **`LoggerAdapter`**. These methods delegate to the underlying logger.

Changed in version 3.6: Attribute **`manager`** and method **`_log()`** were added, which delegate to the underlying logger and allow adapters to be nested.

Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module's shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the **signal** module, you may not be able to use logging from within such handlers. This is because lock implementations in the **threading** module are not always re-entrant, and so cannot be invoked from such signal handlers.

Module-Level Functions

In addition to the classes described above, there are a number of module-level functions.

logging.getLogger(*name*=*None*)

Return a logger with the specified name or, if name is `None`, return a logger which is the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like *'a'*, *'a.b'* or *'a.b.c.d'*. Choice of these names is entirely up to the developer who is using logging.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

logging.getLoggerClass()

Return either the standard **Logger** class, or the last class passed to **setLoggerClass()**. This function may be called from within a new class definition, to ensure that installing a customized **Logger** class will not undo customizations already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

logging.getLogRecordFactory()

Return a callable which is used to create a **LogRecord**.

New in version 3.2: This function has been provided, along with **setLogRecordFactory()**, to allow developers more control over how the **LogRecord** representing a logging event is constructed.

See **setLogRecordFactory()** for more information about the how the factory is called.

logging.debug(*msg*, **args*, ***kwargs*)

Logs a message with level **DEBUG** on the root logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are three keyword arguments in *kwargs* which are inspected: *exc_info* which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by **sys.exc_info()**) or an exception instance is provided, it is used; otherwise, **sys.exc_info()** is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third optional keyword argument is *extra* which can be used to pass a dictionary which is used to populate the _dict_ of the LogRecord created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)s %(clientip)-15s %(user)-8s %(
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logging.warning('Protocol problem: %s', 'connection
```

would print something like:

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs  Protoc
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the **`Formatter`** documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the **`Formatter`** has been set up with a format string which expects ‘clientip’ and ‘user’ in the attribute dictionary of the LogRecord. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is

likely that specialized **Formatter**s would be used with particular **Handler**s.

This function (as well as **info()**, **warning()**, **error()** and **critical()**) will call **basicConfig()** if the root logger doesn't have any handler attached.

Changed in version 3.2: The *stack_info* parameter was added.

logging.info(*msg*, **args*, ***kwargs*)

Logs a message with level **INFO** on the root logger. The arguments are interpreted as for **debug()**.

logging.warning(*msg*, **args*, ***kwargs*)

Logs a message with level **WARNING** on the root logger. The arguments are interpreted as for **debug()**.

Note

There is an obsolete function `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

logging.error(*msg*, **args*, ***kwargs*)

Logs a message with level **ERROR** on the root logger. The arguments are interpreted as for **debug()**.

logging.critical(*msg*, **args*, ***kwargs*)

Logs a message with level **CRITICAL** on the root logger. The arguments are interpreted as for **debug()**.

logging.exception(*msg*, **args*, ***kwargs*)

Logs a message with level **ERROR** on the root logger. The arguments are interpreted as for **debug()**. Exception info is added to the logging message. This function should only be called from an exception handler.

logging.log(*level*, *msg*, **args*, ***kwargs*)

Logs a message with level *level* on the root logger. The other arguments are interpreted as for **debug()**.

logging.disable(*level* = *CRITICAL*)

Provides an overriding level *level* for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *level* and below, so that if you call it with a value of INFO, then all INFO and DEBUG events would be discarded, whereas those of severity WARNING and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

Note that if you have defined any custom logging level higher than `CRITICAL` (this is not recommended), you won't be able to rely on the default value for the *level* parameter, but will have to explicitly supply a suitable value.

Changed in version 3.7: The *level* parameter was defaulted to level `CRITICAL`. See bpo-28524 [https://bugs.python.org/issue?@action=redirect&bpo=28524] for more information about this change.

logging.addLevelName(*level*, *levelName*)

Associates level *level* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a **Formatter** formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

Note

If you are thinking of defining your own levels, please see the section on Custom Levels.

logging.getLevelNamesMapping()

Returns a mapping from level names to their corresponding logging levels. For example, the string “CRITICAL” maps to **`CRITICAL`**. The returned mapping is copied from an internal mapping on each call to this function.

New in version 3.11.

logging.getLevelName(*level*)

Returns the textual or numeric representation of logging level *level*.

If *level* is one of the predefined levels **`CRITICAL`**, **`ERROR`**, **`WARNING`**, **`INFO`** or **`DEBUG`** then you get the corresponding string. If you have associated levels with names using **`addLevelName()`** then the name you have associated with *level* is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned.

The *level* parameter also accepts a string representation of the level such as ‘INFO’. In such cases, this functions returns the corresponding numeric value of the level.

If no matching numeric or string value is passed in, the string ‘Level %s’ % level is returned.

Note

Levels are internally integers (as they need to be compared in the logging logic). This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see LogRecord

attributes), and vice versa.

Changed in version 3.4: In Python versions earlier than 3.4, this function could also be passed a text level, and would return the corresponding numeric value of the level. This undocumented behaviour was considered a mistake, and was removed in Python 3.4, but reinstated in 3.4.2 due to retain backward compatibility.

logging.makeLogRecord(*attrdict*)

Creates and returns a new **LogRecord** instance whose attributes are defined by *attrdict*. This function is useful for taking a pickled **LogRecord** attribute dictionary, sent over a socket, and reconstituting it as a **LogRecord** instance at the receiving end.

logging.basicConfig(***kwargs*)

Does basic configuration for the logging system by creating a **StreamHandler** with a default **Formatter** and adding it to the root logger. The functions **debug()**, **info()**, **warning()**, **error()** and **critical()** will call **basicConfig()** automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured, unless the keyword argument *force* is set to `True`.

Note

This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

Format	Description
filename	Specifies that a `FileHandler` be created, using the specified filename, rather than a `StreamHandler`.
filemode	If *filename* is specified, open the file in this mode. Defaults to `'a'`.
format	Use the specified format string for the handler. Defaults to attributes `levelname`, `name` and `message` separated by colons.
datefmt	Use the specified date/time format, as accepted by `time.strftime()`.
style	If *format* is specified, use this style for the format string. One of `'%'`, `'{'` or `'$'` for printf-style, `str.format()` or `string.Template` respectively. Defaults to `'%'`.
level	Set the root logger level to the specified level.
stream	Use the specified stream to initialize the `StreamHandler`. Note that this argument is incompatible with *filename* - if both are present, a `ValueError` is raised.
handlers	If specified, this should be an iterable of already created handlers to add to the root logger. Any handlers which don't already have a formatter set will be assigned the default formatter created in this function. Note that this argument is incompatible with *filename* or *stream* - if both are present, a `ValueError` is raised.
force	If this keyword argument is specified as true, any existing handlers attached to the root logger are removed and closed, before carrying out the configuration as specified by the other arguments.
encoding	If this keyword argument is specified along with *filename*, its value is used when the `FileHandler` is created, and thus used when opening the output file.
errors	If this keyword argument is specified along with *filename*, its value is used when the `FileHandler` is created, and thus used when opening the output file. If not specified, the value 'backslashreplace' is used. Note that if `None` is specified, it will be passed as such to `open()`, which means that it will be treated the same as passing 'errors'.

Changed in version 3.2: The *style* argument was added.

Changed in version 3.3: The *handlers* argument was added. Additional checks were added to catch situations where incompatible arguments are specified (e.g. *handlers* together with *stream* or *filename*, or *stream* together with *filename*).

Changed in version 3.8: The *force* argument was added.

Changed in version 3.9: The *encoding* and *errors* arguments were added.

logging.shutdown()

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

When the logging module is imported, it registers this function as an exit handler (see **atexit**), so normally there's no need to do that manually.

logging.setLoggerClass(*klass*)

Tells the logging system to use the class *klass* when instantiating a logger. The class should define **__init__()** such that only a name argument is required, and the **__init__()** should call **Logger.__init__()**. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior. After this call, as at any other time, do not instantiate loggers directly using the subclass: continue to use the **logging.getLogger()** API to get your loggers.

logging.setLogRecordFactory(*factory*)

Set a callable which is used to create a **LogRecord**.

Parameters

factory – The factory callable to be used to instantiate a log record.

New in version 3.2: This function has been provided, along

with **getLogRecordFactory()**, to allow developers more control over how the **LogRecord** representing a logging event is constructed.

The factory has the following signature:

```
factory(name, level, fn, lno, msg, args,
exc_info, func=None, sinfo=None, **kwargs)
```

name
: The logger name.

level
: The logging level (numeric).

fn
: The full pathname of the file where the logging call was made.

lno
: The line number in the file where the logging call was made.

msg
: The logging message.

args
: The arguments for the logging message.

exc_info
: An exception tuple, or `None`.

func
: The name of the function or method which invoked the logging call.

sinfo
: A stack traceback such as is provided by **traceback.print_stack()**, showing the call hierarchy.

kwargs

Additional keyword arguments.

Module-Level Attributes

logging.lastResort

A "handler of last resort" is available through this attribute. This is a **StreamHandler** writing to `sys.stderr` with a level of `WARNING`, and is used to handle logging events in the absence of any logging configuration. The end result is to just print the message to `sys.stderr`. This replaces the earlier error message saying that "no handlers could be found for logger XYZ". If you need the earlier behaviour for some reason, `lastResort` can be set to `None`.

New in version 3.2.

Integration with the warnings module

The **captureWarnings()** function can be used to integrate **logging** with the **warnings** module.

logging.captureWarnings(*capture*)

This function is used to turn the capture of warnings by logging on and off.

If *capture* is `True`, warnings issued by the **warnings** module will be redirected to the logging system. Specifically, a warning will be formatted using **warnings.formatwarning()** and the resulting string logged to a logger named `'py.warnings'` with a severity of **WARNING**.

If *capture* is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

- Logging Cookbook

This section describes the API for configuring the logging module.

Configuration functions

The following functions configure the logging module. They are located in the `logging.config` module. Their use is optional — you can configure the logging module using these functions or by making calls to the main API (defined in `logging` itself) and defining handlers which are declared either in `logging` or `logging.handlers`.

logging.config.dictConfig(*config*)

Takes the logging configuration from a dictionary. The contents of this dictionary are described in Configuration dictionary schema below.

If an error is encountered during configuration, this function will raise a `ValueError`, `TypeError`, `AttributeError` or `ImportError` with a suitably descriptive message. The

following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An id which does not have a corresponding destination.
- A non-existent handler id found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the **DictConfigurator** class, whose constructor is passed the dictionary used for configuration, and has a **configure()** method. The **logging.config** module has a callable attribute **dictConfigClass** which is initially set to **DictConfigurator**. You can replace the value of **dictConfigClass** with a suitable implementation of your own.

dictConfig() calls **dictConfigClass** passing the specified dictionary, and then calls the **configure()** method on the returned object to put the configuration into effect:

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of **DictConfigurator** could call `DictConfigurator.__init__()` in its own **__init__()**, then set up custom prefixes which would be usable in the subsequent **configure()** call. **dictConfigClass** would be bound to this new subclass, and then **dictConfig()** could be called exactly as in the default, uncustomized state.

New in version 3.2.

logging.config.fileConfig(*fname*, *defaults=None*,

disable_existing_loggers=True, *encoding=None*)

Reads the logging configuration from a **configparser**-format file. The format of the file should be as described in Configuration file format. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

Parameters

- **fname** – A filename, or a file-like object, or an instance derived from **RawConfigParser**. If a `RawConfigParser`-derived instance is passed, it is used as is. Otherwise, a **Configparser** is instantiated, and the configuration read by it from the object passed in `fname`. If that has a **readline()** method, it is assumed to be a file-like object and read using **read_file()**; otherwise, it is assumed to be a filename and passed to **read()**.
- **defaults** – Defaults to be passed to the ConfigParser can be specified in this argument.
- **disable_existing_loggers** –

  If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing non-root loggers unless they or their ancestors are explicitly named in the logging configuration.

  param encoding

The encoding used to open file when *fname* is filename.

Changed in version 3.4: An instance of a subclass of **RawConfigParser** is now accepted as a value for `fname`. This facilitates:

- Use of a configuration file where logging configuration is just part of the overall application configuration.
- Use of a configuration read from a file, and then modified by the using application (e.g. based on command-line parameters or other aspects of the runtime environment) before being passed to `fileConfig`.

New in version 3.10: The *encoding* parameter is added.

logging.config.listen(*port=DEFAULT_LOGGING_CONFIG_PORT*, *verify=None*)

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default **DEFAULT_LOGGING_CONFIG_PORT** is used. Logging configurations will be sent as a file suitable for processing by **dictConfig()** or **fileConfig()**. Returns a **Thread** instance on which you can call **start()** to start the server, and which you can **join()** when appropriate. To stop the server, call **stopListening()**.

The `verify` argument, if specified, should be a callable which should verify whether bytes received across the socket are valid and should be processed. This could be done by encrypting and/or signing what is sent across the socket, such that the `verify` callable can perform signature verification and/or decryption. The `verify` callable is called with a single argument - the bytes received across the socket - and

should return the bytes to be processed, or `None` to indicate that the bytes should be discarded. The returned bytes could be the same as the passed in bytes (e.g. when only verification is done), or they could be completely different (perhaps if decryption were performed).

To send a configuration to the socket, read in the configuration file and send it to the socket as a sequence of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

Note

Because portions of the configuration are passed through **`eval()`**, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls **`listen()`**. Specifically, if the process calling **`listen()`** runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's **`listen()`** socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used. To avoid the risk of this happening, use the `verify` argument to **`listen()`** to prevent unrecognised configurations from being applied.

Changed in version 3.4: The `verify` argument was added.

Note

If you want to send configurations to the listener which don't disable existing loggers, you will need to use a JSON format for the configuration, which will use **`dictConfig()`** for configuration. This method allows you

to specify `disable_existing_loggers` as `False` in the configuration you send.

logging.config.stopListening()

Stops the listening server which was created with a call to **`listen()`**. This is typically called before calling **`join()`** on the return value from **`listen()`**.

Security considerations

The logging configuration functionality tries to offer convenience, and in part this is done by offering the ability to convert text in configuration files into Python objects used in logging configuration - for example, as described in User-defined objects. However, these same mechanisms (importing callables from user-defined modules and calling them with parameters from the configuration) could be used to invoke any code you like, and for this reason you should treat configuration files from untrusted sources with *extreme caution* and satisfy yourself that nothing bad can happen if you load them, before actually loading them.

Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named 'console' and then say that the logger named 'startup' will send its messages to the 'console' handler. These objects aren't limited to those provided by the **`logging`** module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in Object connections below.

Dictionary Schema Details

The dictionary passed to **`dictConfig()`** must contain the

following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a 'configuring dict' is mentioned, it will be checked for the special `'()'` key to see if a custom instantiation is required. If so, the mechanism described in User-defined objects below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding **`Formatter`** instance.

  The configuring dict is searched for the following optional keys which correspond to the arguments passed to create a **`Formatter`** object:

  - `format`
  - `datefmt`
  - `style`
  - `validate` (since version >=3.8)

  An optional `class` key indicates the name of the formatter's class (as a dotted module and class name). The instantiation arguments are as for **`Formatter`**, thus this key is most useful for instantiating a customised subclass of **`Formatter`**. For example, the alternative class might present exception tracebacks in an expanded or condensed format. If your formatter requires different or extra configuration keys, you should use User-defined objects.

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding Filter instance.

  The configuring dict is searched for the key `name` (defaulting

to the empty string) and this is used to construct a **`logging.Filter`** instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding Handler instance.

  The configuring dict is searched for the following keys:

  - `class` (mandatory). This is the fully qualified name of the handler class.
  - `level` (optional). The level of the handler.
  - `formatter` (optional). The id of the formatter for this handler.
  - `filters` (optional). A list of ids of the filters for this handler.

    Changed in version 3.11: `filters` can take filter instances in addition to ids.

  All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet:

```
handlers:
  console:
    class : logging.StreamHandler
    formatter: brief
    level   : INFO
    filters: [allow_foo]
    stream  : ext://sys.stdout
  file:
    class : logging.handlers.RotatingFileHandler
    formatter: precise
    filename: logconfig.log
    maxBytes: 1024
    backupCount: 3
```

  the handler with id `console` is instantiated as a

logging.StreamHandler, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a **logging.handlers.RotatingFileHandler** with the keyword arguments `filename='logconfig.log', maxBytes=1024, backupCount=3`.

- *loggers* - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

  The configuring dict is searched for the following keys:

  - `level` (optional). The level of the logger.
  - `propagate` (optional). The propagation setting of the logger.
  - `filters` (optional). A list of ids of the filters for this logger.

    Changed in version 3.11: `filters` can take filter instances in addition to ids.

  - `handlers` (optional). A list of ids of the handlers for this logger.

  The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- *root* - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.

- *incremental* - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing **fileConfig()** API.

  If the specified value is `True`, the configuration is processed as described in the section on Incremental Configuration.

- *disable_existing_loggers* - whether any existing non-root loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter defaults to `True`. This value is ignored if *incremental* is `True`.

Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular

logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes h
  precise:
    # configuration for formatter with id 'precise' goes
handlers:
  h1: #This is an id
   # configuration of handler with id 'h1' goes here
   formatter: brief
  h2: #This is another id
   # configuration of handler with id 'h2' goes here
   formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a 'factory' - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key `'()'`. Here's a concrete example:

```
formatters:
  brief:
    format: '%(message)s'
  default:
    format: '%(asctime)s %(levelname)-8s %(name)-15s %(m
    datefmt: '%Y-%m-%d %H:%M:%S'
  custom:
      (): my.package.customFormatterFactory
      bar: baz
      spam: 99.9
      answer: 42
```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard **`logging.Formatter`** instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in

a **logging.Formatter** initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```
{
  'format' : '%(message)s'
}
```

and:

```
{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key `'()'`, the instantiation is inferred from the context: as a result, standard **logging.Formatter** instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42
}
```

and this contains the special key `'()'`, which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```
my.package.customFormatterFactory(bar='baz', spam=99.9,
```

The key `'()'` has been used as the special key because it is not a

valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The `'()'` also serves as a mnemonic that the corresponding value is a callable.

> *Changed in version 3.11:* The `filters` member of `handlers` and `loggers` can take filter instances in addition to ids.

You can also specify a special key `'.'` whose value is a dictionary is a mapping of attribute names to values. If found, the specified attributes will be set on the user-defined object before it is returned. Thus, with the following configuration:

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42,
  '.' {
    'foo': 'bar',
    'baz': 'bozz'
  }
}
```

the returned formatter will have attribute `foo` set to `'bar'` and attribute `baz` set to `'bozz'`.

Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value

processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+)://(?P<suffix>.*)$` whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a `level` in a logger or handler will automatically be converted to the value `logging.DEBUG`, and the `handlers`, `filters` and `formatter` entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the **`logging`** module. For example, consider **`logging.handlers.MemoryHandler`**, which takes a `target` argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given `target` just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a `my.package.MyHandler` which has an `alternate` handler, the configuration system would not know that the `alternate` referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
  file:
    # configuration of file handler goes here

  custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string `'cfg://handlers.file'` will be resolved in an analogous way to strings with the `ext://` prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by `str.format`. Thus, given the following snippet:

```
handlers:
  email:
    class: logging.handlers.SMTPHandler
    mailhost: localhost
    fromaddr: my_app@domain.tld
    toaddrs:
      - support_team@domain.tld
      - dev_team@domain.tld
    subject: Houston, we have a problem.
```

in the configuration, the string `'cfg://handlers'` would resolve to the dict with key `handlers`, the string `'cfg://handlers.email` would resolve to the dict with key `email` in the `handlers` dict, and so on. The string `'cfg://handlers.email.toaddrs[1]` would resolve to `'dev_team@domain.tld'` and the string `'cfg://handlers.email.toaddrs[0]'` would resolve to the value `'support_team@domain.tld'`. The `subject` value could be accessed using either `'cfg://handlers.email.subject'` or, equivalently, `'cfg://handlers.email[subject]'`. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string `cfg://handlers.myhandler.mykey.123`, this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.

Import resolution and custom importers

Import resolution, by default, uses the builtin **`__import__()`** function to do its importing. You may want to replace this with your own importing mechanism: if so, you can replace the **`importer`** attribute of the **`DictConfigurator`** or its superclass, the **`BaseConfigurator`** class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with **`staticmethod()`**. For example:

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with **`staticmethod()`** if you're setting the import callable on a configurator *instance*.

Configuration file format

The configuration file format understood by **`fileConfig()`** is based on **`configparser`** functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

Note

The **`fileConfig()`** API is older than the **`dictConfig()`** API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure **`Filter`** objects, which provide for filtering of messages beyond simple integer levels, using **`fileConfig()`**. If you need to have instances of **`Filter`** in your logging configuration, you will need to use **`dictConfig()`**. Note that future enhancements to configuration functionality will be added to **`dictConfig()`**, so it's worth considering transitioning to this newer API when it's convenient to do so.

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,ha

[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,fo
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are evaluated in the context of the `logging` package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information

is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by **`eval()`** in the `logging` package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean 'log everything'.

The `formatter` entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging._defaultFormatter`) is used. If a name is specified, it must appear in the `[formatters]` section and have a corresponding section in the configuration file.

The `args` entry, when evaluated in the context of the `logging` package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant

handlers, or to the examples below, to see how typical entries are constructed. If not provided, it defaults to `()`.

The optional `kwargs` entry, when evaluated in the context of the `logging` package's namespace, is the keyword argument dict to the constructor for the handler class. If not provided, it defaults to `{}`.

```
[handler_hand02]
class=FileHandler
level=DEBUG
formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
level=ERROR
formatter=form05
args=(('localhost', handlers.SYSLOG_UDP_PORT), handlers.

[handler_hand06]
class=handlers.NTEventLogHandler
level=CRITICAL
formatter=form06
args=('Python Application', '', 'Application')

[handler_hand07]
class=handlers.SMTPHandler
```

```
level=WARN
formatter=form07
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'
kwargs={'timeout': 10.0}

[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
args=(10, ERROR)

[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')
kwargs={'secure': True}
```

Sections which specify formatter configuration are typified by the following.

```
[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s
datefmt=
style=%
validate=True
class=logging.Formatter
```

The arguments for the formatter configuration are the same as the keys in the dictionary schema formatters section.

Note

Due to the use of **`eval()`** as described above, there are potential security risks which result from using the **`listen()`** to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the **`listen()`** documentation for more

information.

`logging.handlers` — Logging handlers

Source code: Lib/logging/handlers.py [https://github.com/python/cpython/tree/3.11/Lib/logging/handlers.py]

Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

The following useful handlers are provided in the package. Note that three of the handlers (`StreamHandler`, `FileHandler` and `NullHandler`) are actually defined in the `logging` module itself, but have been documented here along with the other handlers.

StreamHandler

The `StreamHandler` class, located in the core `logging` package, sends logging output to streams such as *sys.stdout*, *sys.stderr* or any file-like object (or, more precisely, any object which supports `write()` and `flush()` methods).

class logging.StreamHandler(*stream=None*)

Returns a new instance of the `StreamHandler` class. If *stream* is specified, the instance will use it for logging output; otherwise, *sys.stderr* will be used.

emit(*record*)

If a formatter is specified, it is used to format the

record. The record is then written to the stream followed by **terminator**. If exception information is present, it is formatted using **traceback.print_exception()** and appended to the stream.

flush()

Flushes the stream by calling its **flush()** method. Note that the **close()** method is inherited from **Handler** and so does no output, so an explicit **flush()** call may be needed at times.

setStream(*stream*)

Sets the instance's stream to the specified value, if it is different. The old stream is flushed before the new stream is set.

Parameters

stream – The stream that the handler should use.

Returns

the old stream, if the stream was changed, or *None* if it wasn't.

New in version 3.7.

terminator

String used as the terminator when writing a formatted record to a stream. Default value is `'\n'`.

If you don't want a newline termination, you can set the handler instance's `terminator` attribute to the empty string.

In earlier versions, the terminator was hardcoded as `'\n'`.

New in version 3.2.

FileHandler

The **FileHandler** class, located in the core **logging** package, sends logging output to a disk file. It inherits the output functionality from **StreamHandler**.

class logging.FileHandler(*filename*, *mode*='a', *encoding*=*None*, *delay*=*False*, *errors*=*None*)

Returns a new instance of the **FileHandler** class. The specified file is opened and used as the stream for logging. If *mode* is not specified, **'a'** is used. If *encoding* is not None, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to **emit()**. By default, the file grows indefinitely. If *errors* is specified, it's used to determine how encoding errors are handled.

Changed in version 3.6: As well as string values, **Path** objects are also accepted for the *filename* argument.

Changed in version 3.9: The *errors* parameter was added.

close()

Closes the file.

emit(*record*)

Outputs the record to the file.

Note that if the file was closed due to logging shutdown at exit and the file mode is 'w', the record will not be emitted (see bpo-42378 [https://bugs.python.org/issue?@action=redirect&bpo=42378]).

NullHandler

New in version 3.1.

The **NullHandler** class, located in the core **logging** package, does not do any formatting or output. It is essentially a 'no-op'

handler for use by library developers.

class logging.NullHandler

Returns a new instance of the **`NullHandler`** class.

emit(*record*)

This method does nothing.

handle(*record*)

This method does nothing.

createLock()

This method returns `None` for the lock, since there is no underlying I/O to which access needs to be serialized.

See Configuring Logging for a Library for more information on how to use **`NullHandler`**.

WatchedFileHandler

The **`WatchedFileHandler`** class, located in the **`logging.handlers`** module, is a **`FileHandler`** which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as *newsyslog* and *logrotate* which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, *ST_INO* is not supported under

Windows; **stat()** always returns zero for this value.

class logging.handlers.WatchedFileHandler(*filename*, *mode*='a', *encoding*=*None*, *delay*=*False*, *errors*=*None*)

Returns a new instance of the **WatchedFileHandler** class. The specified file is opened and used as the stream for logging. If *mode* is not specified, **'a'** is used. If *encoding* is not `None`, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to **emit()**. By default, the file grows indefinitely. If *errors* is provided, it determines how encoding errors are handled.

Changed in version 3.6: As well as string values, **Path** objects are also accepted for the *filename* argument.

Changed in version 3.9: The *errors* parameter was added.

reopenIfNeeded()

Checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, typically as a precursor to outputting the record to the file.

New in version 3.6.

emit(*record*)

Outputs the record to the file, but first calls **reopenIfNeeded()** to reopen the file if it has changed.

BaseRotatingHandler

The **BaseRotatingHandler** class, located in the **logging.handlers** module, is the base class for the rotating file handlers, **RotatingFileHandler** and **TimedRotatingFileHandler**. You should not need to instantiate this class, but it has attributes and methods you may need to override.

class logging.handlers.BaseRotatingHandler(*filename*, *mode*, *encoding*=*None*, *delay*=*False*, *errors*=*None*)

The parameters are as for **`FileHandler`**. The attributes are:

namer

If this attribute is set to a callable, the **`rotation_filename()`** method delegates to this callable. The parameters passed to the callable are those passed to **`rotation_filename()`**.

Note

The namer function is called quite a few times during rollover, so it should be as simple and as fast as possible. It should also return the same output every time for a given input, otherwise the rollover behaviour may not work as expected.

It's also worth noting that care should be taken when using a namer to preserve certain attributes in the filename which are used during rotation. For example, **`RotatingFileHandler`** expects to have a set of log files whose names contain successive integers, so that rotation works as expected, and **`TimedRotatingFileHandler`** deletes old log files (based on the `backupCount` parameter passed to the handler's initializer) by determining the oldest files to delete. For this to happen, the filenames should be sortable using the date/time portion of the filename, and a namer needs to respect this. (If a namer is wanted that doesn't respect this scheme, it will need to be used in a subclass of **`TimedRotatingFileHandler`** which overrides the **`getFilesToDelete()`** method to fit in with the custom naming scheme.)

New in version 3.3.

rotator

If this attribute is set to a callable, the `rotate()` method delegates to this callable. The parameters passed to the callable are those passed to `rotate()`.

New in version 3.3.

rotation_filename(*default_name*)

Modify the filename of a log file when rotating.

This is provided so that a custom filename can be provided.

The default implementation calls the 'namer' attribute of the handler, if it's callable, passing the default name to it. If the attribute isn't callable (the default is `None`), the name is returned unchanged.

Parameters

default_name – The default name for the log file.

New in version 3.3.

rotate(*source*, *dest*)

When rotating, rotate the current log.

The default implementation calls the 'rotator' attribute of the handler, if it's callable, passing the source and dest arguments to it. If the attribute isn't callable (the default is `None`), the source is simply renamed to the destination.

Parameters

- **source** – The source filename. This is normally the base filename, e.g. 'test.log'.
- **dest** – The destination filename. This is normally what the source is rotated to, e.g. 'test.log.1'.

New in version 3.3.

The reason the attributes exist is to save you having to subclass - you can use the same callables for instances of **RotatingFileHandler** and **TimedRotatingFileHandler**. If either the namer or rotator callable raises an exception, this will be handled in the same way as any other exception during an **emit()** call, i.e. via the **handleError()** method of the handler.

If you need to make more significant changes to rotation processing, you can override the methods.

For an example, see Using a rotator and namer to customize log rotation processing.

RotatingFileHandler

The **RotatingFileHandler** class, located in the **logging.handlers** module, supports rotation of disk log files.

class logging.handlers.RotatingFileHandler(*filename*, *mode*='a', *maxBytes*=0, *backupCount*=0, *encoding*=None, *delay*=False, *errors*=None)

Returns a new instance of the **RotatingFileHandler** class. The specified file is opened and used as the stream for logging. If *mode* is not specified, `'a'` is used. If *encoding* is not `None`, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to **emit()**. By default, the file grows indefinitely. If *errors* is provided, it determines how encoding errors are handled.

You can use the *maxBytes* and *backupCount* values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly *maxBytes* in length; but if either of *maxBytes* or *backupCount* is zero, rollover never occurs, so you generally want to set *backupCount* to at least 1, and have a non-zero *maxBytes*. When *backupCount* is non-zero, the system

will save old log files by appending the extensions '.1', '.2' etc., to the filename. For example, with a *backupCount* of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

Changed in version 3.6: As well as string values, **`Path`** objects are also accepted for the *filename* argument.

Changed in version 3.9: The *errors* parameter was added.

doRollover()

Does a rollover, as described above.

emit(*record*)

Outputs the record to the file, catering for rollover as described previously.

TimedRotatingFileHandler

The **`TimedRotatingFileHandler`** class, located in the **`logging.handlers`** module, supports rotation of disk log files at certain timed intervals.

class logging.handlers.TimedRotatingFileHandler(*filename*, *when='h'*, *interval=1*, *backupCount=0*, *encoding=None*, *delay=False*, *utc=False*, *atTime=None*, *errors=None*)

Returns a new instance of the **`TimedRotatingFileHandler`** class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of *when* and *interval*.

You can use the *when* to specify the type of *interval*. The list of possible values is below. Note that they are not case sensitive.

Type of interval	Meaning of *interval*
`'S'`	Seconds
`'M'`	Minutes
`'H'`	Hours
`'D'`	Days
`'W0'`–`'W6'`	Weekday (0=Monday)
`'midnight'`	Roll over at midnight, if *atTime* not specified, else at time *atTime*

When using weekday-based rotation, specify ‘W0’ for Monday, ‘W1’ for Tuesday, and so on up to ‘W6’ for Sunday. In this case, the value passed for *interval* isn’t used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to **`emit()`**.

If *atTime* is not `None`, it must be a `datetime.time` instance which specifies the time of day when rollover occurs, for the cases where rollover is set to happen “at midnight” or “on a particular weekday”. Note that in these cases, the *atTime* value is effectively used to compute the *initial* rollover, and subsequent rollovers would be calculated via the normal

interval calculation.

If *errors* is specified, it's used to determine how encoding errors are handled.

Note

Calculation of the initial rollover time is done when the handler is initialised. Calculation of subsequent rollover times is done only when rollover occurs, and rollover occurs only when emitting output. If this is not kept in mind, it might lead to some confusion. For example, if an interval of "every minute" is set, that does not mean you will always see log files with times (in the filename) separated by a minute; if, during application execution, logging output is generated more frequently than once a minute, *then* you can expect to see log files with times separated by a minute. If, on the other hand, logging messages are only output once every five minutes (say), then there will be gaps in the file times corresponding to the minutes where no output (and hence no rollover) occurred.

Changed in version 3.4: atTime parameter was added.

Changed in version 3.6: As well as string values, **`Path`** objects are also accepted for the *filename* argument.

Changed in version 3.9: The *errors* parameter was added.

doRollover()

Does a rollover, as described above.

emit(*record*)

Outputs the record to the file, catering for rollover as described above.

getFilesToDelete()

Returns a list of filenames which should be deleted as

part of rollover. These are the absolute paths of the oldest backup log files written by the handler.

SocketHandler

The **SocketHandler** class, located in the **logging.handlers** module, sends logging output to a network socket. The base class uses a TCP socket.

class logging.handlers.SocketHandler(*host*, *port*)

Returns a new instance of the **SocketHandler** class intended to communicate with a remote machine whose address is given by *host* and *port*.

Changed in version 3.4: If `port` is specified as `None`, a Unix domain socket is created using the value in `host` - otherwise, a TCP socket is created.

close()

Closes the socket.

emit()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a **LogRecord**, use the **makeLogRecord()** function.

handleError()

Handles an error which has occurred during **emit()**. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

makeSocket()

This is a factory method which allows subclasses to define the precise type of socket they want. The default

implementation creates a TCP socket (**`socket.SOCK_STREAM`**).

makePickle(*record*)

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket. The details of this operation are equivalent to:

```
data = pickle.dumps(record_attr_dict, 1)
datalen = struct.pack('>L', len(data))
return datalen + data
```

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

send(*packet*)

Send a pickled byte-string *packet* to the socket. The format of the sent byte-string is as described in the documentation for **`makePickle()`**.

This function allows for partial sends, which can happen when the network is busy.

createSocket()

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- `retryStart` (initial delay, defaulting to 1.0 seconds).
- `retryFactor` (multiplier, defaulting to 2.0).
- `retryMax` (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

DatagramHandler

The **`DatagramHandler`** class, located in the **`logging.handlers`** module, inherits from **`SocketHandler`** to support sending logging messages over UDP sockets.

class logging.handlers.DatagramHandler(*host*, *port*)

Returns a new instance of the **`DatagramHandler`** class intended to communicate with a remote machine whose address is given by *host* and *port*.

Note

As UDP is not a streaming protocol, there is no persistent connection between an instance of this handler and *host*. For this reason, when using a network socket, a DNS lookup might have to be made each time an event is logged, which can introduce some latency into the system. If this affects you, you can do a lookup yourself and initialize this handler using the looked-up IP address rather than the hostname.

Changed in version 3.4: If `port` is specified as `None`, a Unix domain socket is created using the value in `host` -

otherwise, a UDP socket is created.

emit()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a **`LogRecord`**, use the **`makeLogRecord()`** function.

makeSocket()

The factory method of **`SocketHandler`** is here overridden to create a UDP socket (**`socket.SOCK_DGRAM`**).

send(*s*)

Send a pickled byte-string to a socket. The format of the sent byte-string is as described in the documentation for **`SocketHandler.makePickle()`**.

SysLogHandler

The **`SysLogHandler`** class, located in the **`logging.handlers`** module, supports sending logging messages to a remote or local Unix syslog.

class logging.handlers.SysLogHandler(*address=('localhost', SYSLOG_UDP_PORT)*, *facility=LOG_USER*, *socktype=socket.SOCK_DGRAM*)

Returns a new instance of the **`SysLogHandler`** class intended to communicate with a remote Unix machine whose address is given by *address* in the form of a `(host, port)` tuple. If *address* is not specified, `('localhost', 514)` is used. The address is used to open a socket. An alternative to providing a `(host, port)` tuple is providing an address as a string, for example '/dev/log'. In this case, a Unix domain socket is used to send the message to the syslog. If *facility* is not specified, **`LOG_USER`** is used. The type of socket opened

depends on the *socktype* argument, which defaults to **socket.SOCK_DGRAM** and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of **socket.SOCK_STREAM**.

Note that if your server is not listening on UDP port 514, **SysLogHandler** may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually '/dev/log' but on OS/X it's '/var/run/syslog'. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

Note

On macOS 12.x (Monterey), Apple has changed the behaviour of their syslog daemon - it no longer listens on a domain socket. Therefore, you cannot expect **SysLogHandler** to work on this system.

See gh-91070 [https://github.com/python/cpython/issues/91070] for more information.

Changed in version 3.2: socktype was added.

close()

Closes the socket to the remote host.

createSocket()

Tries to create a socket and, if it's not a datagram socket, connect it to the other end. This method is called during handler initialization, but it's not regarded as an error if the other end isn't listening at this point - the method will be called again when emitting an event, if but it's not regarded as an error if the other end isn't listening yet — the method will be called again when emitting an event, if there is no

socket at that point.

New in version 3.11.

emit(*record*)

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

Changed in version 3.2.1: (See: bpo-12168 [https://bugs.python.org/issue?@action=redirect&bpo=12168].) In earlier versions, the message sent to the syslog daemons was always terminated with a NUL byte, because early versions of these daemons expected a NUL terminated message - even though it's not in the relevant specification (**RFC 5424** [https://datatracker.ietf.org/doc/html/rfc5424.html]). More recent versions of these daemons don't expect the NUL byte but strip it off if it's there, and even more recent daemons (which adhere more closely to RFC 5424) pass the NUL byte on as part of the message.

To enable easier handling of syslog messages in the face of all these differing daemon behaviours, the appending of the NUL byte has been made configurable, through the use of a class-level attribute, `append_nul`. This defaults to `True` (preserving the existing behaviour) but can be set to `False` on a `SysLogHandler` instance in order for that instance to *not* append the NUL terminator.

Changed in version 3.3: (See: bpo-12419 [https://bugs.python.org/issue?@action=redirect&bpo=12419].) In earlier versions, there was no facility for an "ident" or "tag" prefix to identify the source of the message. This can now be specified using a class-level attribute, defaulting to `""` to preserve existing behaviour, but which can be overridden on a `SysLogHandler` instance in order for that instance to prepend the ident to every message handled. Note that the provided ident

must be text, not bytes, and is prepended to the message exactly as is.

encodePriority(*facility*, *priority*)

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic `LOG_` values are defined in **`SysLogHandler`** and mirror the values defined in the `sys/syslog.h` header file.

Priorities

Name (string)	Symbolic value
alert	LOG_ALERT
crit or critical	LOG_CRIT
debug	LOG_DEBUG
emerg or panic	LOG_EMERG
err or error	LOG_ERR
info	LOG_INFO
notice	LOG_NOTICE
warn or warning	LOG_WARNING

Facilities

Name (string)	Symbolic value
auth	LOG_AUTH
authpriv	LOG_AUTHPRIV
cron	LOG_CRON
daemon	LOG_DAEMON
ftp	LOG_FTP
kern	LOG_KERN
lpr	LOG_LPR
mail	LOG_MAIL
news	LOG_NEWS
syslog	LOG_SYSLOG
user	LOG_USER
uucp	LOG_UUCP

LOG_LOCAL0	
LOG_LOCAL1	
LOG_LOCAL2	
LOG_LOCAL3	
LOG_LOCAL4	
LOG_LOCAL5	
LOG_LOCAL6	
LOG_LOCAL7	

mapPriority(*levelname*)

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL` to the equivalent syslog names, and all other level names to 'warning'.

NTEventLogHandler

The **`NTEventLogHandler`** class, located in the **`logging.handlers`** module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond's Win32 extensions for Python installed.

class logging.handlers.NTEventLogHandler(*appname*, *dllname=None*, *logtype='Application'*)

Returns a new instance of the **`NTEventLogHandler`** class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, `'win32service.pyd'` is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the

name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of `'Application'`, `'System'` or `'Security'`, and defaults to `'Application'`.

close()

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

emit(*record*)

Determines the message ID, event category and event type, and then logs the message in the NT event log.

getEventCategory(*record*)

Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

getEventType(*record*)

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's typemap attribute, which is set up in **`__init__()`** to a dictionary which contains mappings for **`DEBUG`**, **`INFO`**, **`WARNING`**, **`ERROR`** and **`CRITICAL`**. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's *typemap* attribute.

getMessageID(*record*)

Returns the message ID for the record. If you are using your own messages, you could do this by having the *msg* passed to the logger being an ID rather than a

format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`.

SMTPHandler

The **`SMTPHandler`** class, located in the **`logging.handlers`** module, supports sending logging messages to an email address via SMTP.

class logging.handlers.SMTPHandler(*mailhost*, *fromaddr*, *toaddrs*, *subject*, *credentials*=*None*, *secure*=*None*, *timeout*=*1.0*)

Returns a new instance of the **`SMTPHandler`** class. The instance is initialized with the from and to addresses and subject line of the email. The *toaddrs* should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the *mailhost* argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the *credentials* argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the *secure* argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the **`smtplib.SMTP.starttls()`** method.)

A timeout can be specified for communication with the SMTP server using the *timeout* argument.

New in version 3.3: The *timeout* argument was added.

emit(*record*)

Formats the record and sends it to the specified addressees.

getSubject(*record*)

If you want to specify a subject line which is record-dependent, override this method.

MemoryHandler

The **MemoryHandler** class, located in the **logging.handlers** module, supports buffering of logging records in memory, periodically flushing them to a *target* handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

MemoryHandler is a subclass of the more general **BufferingHandler**, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling **shouldFlush()** to see if the buffer should be flushed. If it should, then **flush()** is expected to do the flushing.

class logging.handlers.BufferingHandler(*capacity*)

Initializes the handler with a buffer of the specified capacity. Here, *capacity* means the number of logging records buffered.

emit(*record*)

Append the record to the buffer. If **shouldFlush()** returns true, call **flush()** to process the buffer.

flush()

You can override this to implement custom flushing behavior. This version just zaps the buffer to empty.

shouldFlush(*record*)

Return `True` if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

class logging.handlers.MemoryHandler(*capacity*, *flushLevel*=*ERROR*, *target*=*None*, *flushOnClose*=*True*)

Returns a new instance of the **MemoryHandler** class. The instance is initialized with a buffer size of *capacity* (number of records buffered). If *flushLevel* is not specified, **ERROR** is used. If no *target* is specified, the target will need to be set using **setTarget()** before this handler does anything useful. If *flushOnClose* is specified as `False`, then the buffer is *not* flushed when the handler is closed. If not specified or specified as `True`, the previous behaviour of flushing the buffer will occur when the handler is closed.

Changed in version 3.6: The *flushOnClose* parameter was added.

close()

Calls **flush()**, sets the target to `None` and clears the buffer.

flush()

For a **MemoryHandler**, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when this happens. Override if you want different behavior.

setTarget(*target*)

Sets the target handler for this handler.

shouldFlush(*record*)

Checks for buffer full or a record at the *flushLevel* or higher.

HTTPHandler

The **HTTPHandler** class, located in the **logging.handlers** module, supports sending logging messages to a web server, using either `GET` or `POST` semantics.

class logging.handlers.HTTPHandler(*host*, *url*, *method*='*GET*',

secure=*False*, *credentials*=*None*, *context*=*None*)

Returns a new instance of the **HTTPHandler** class. The *host* can be of the form `host:port`, should you need to use a specific port number. If no *method* is specified, `GET` is used. If *secure* is true, a HTTPS connection will be used. The *context* parameter may be set to a **ssl.SSLContext** instance to configure the SSL settings used for the HTTPS connection. If *credentials* is specified, it should be a 2-tuple consisting of userid and password, which will be placed in a HTTP 'Authorization' header using Basic authentication. If you specify credentials, you should also specify secure=True so that your userid and password are not passed in cleartext across the wire.

Changed in version 3.5: The *context* parameter was added.

mapLogRecord(*record*)

Provides a dictionary, based on `record`, which is to be URL-encoded and sent to the web server. The default implementation just returns `record.__dict__`. This method can be overridden if e.g. only a subset of **LogRecord** is to be sent to the web server, or if more specific customization of what's sent to the server is required.

emit(*record*)

Sends the record to the web server as a URL-encoded dictionary. The **mapLogRecord()** method is used to convert the record to the dictionary to be sent.

Note

Since preparing a record for sending it to a web server is not the same as a generic formatting operation, using **setFormatter()** to specify a **Formatter** for a **HTTPHandler** has no effect. Instead of calling **format()**, this handler calls **mapLogRecord()** and then **urllib.parse.urlencode()** to encode the dictionary in a form suitable for sending to a web server.

QueueHandler

New in version 3.2.

The **QueueHandler** class, located in the **logging.handlers** module, supports sending logging messages to a queue, such as those implemented in the **queue** or **multiprocessing** modules.

Along with the **QueueListener** class, **QueueHandler** can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via **SMTPHandler**) are done on a separate thread.

class logging.handlers.QueueHandler(*queue*)

Returns a new instance of the **QueueHandler** class. The instance is initialized with the queue to send messages to. The *queue* can be any queue-like object; it's used as-is by the **enqueue()** method, which needs to know how to send messages to it. The queue is not *required* to have the task tracking API, which means that you can use **SimpleQueue** instances for *queue*.

Note

If you are using **multiprocessing**, you should avoid using **SimpleQueue** and instead use **multiprocessing.Queue**.

emit(*record*)

Enqueues the result of preparing the LogRecord. Should an exception occur (e.g. because a bounded queue has filled up), the **handleError()** method is called to handle the error. This can result in the record silently being dropped (if **logging.raiseExceptions** is `False`) or a message printed to `sys.stderr` (if

logging.raiseExceptions is `True`).

prepare(*record*)

Prepares a record for queuing. The object returned by this method is enqueued.

The base implementation formats the record to merge the message, arguments, exception and stack information, if present. It also removes unpickleable items from the record in-place. Specifically, it overwrites the record's **msg** and **message** attributes with the merged message (obtained by calling the handler's **format()** method), and sets the **args**, **exc_info** and **exc_text** attributes to `None`.

You might want to override this method if you want to convert the record to a dict or JSON string, or send a modified copy of the record while leaving the original intact.

Note

The base implementation formats the message with arguments, sets the `message` and `msg` attributes to the formatted message and sets the `args` and `exc_text` attributes to `None` to allow pickling and to prevent further attempts at formatting. This means that a handler on the **QueueListener** side won't have the information to do custom formatting, e.g. of exceptions. You may wish to subclass `QueueHandler` and override this method to e.g. avoid setting `exc_text` to `None`. Note that the `message` / `msg` / `args` changes are related to ensuring the record is pickleable, and you might or might not be able to avoid doing that depending on whether your `args` are pickleable. (Note that you may have to consider not only your own code but also code in any libraries that you use.)

enqueue(*record*)

Enqueues the record on the queue using `put_nowait()`; you may want to override this if you want to use blocking behaviour, or a timeout, or a customized queue implementation.

QueueListener

New in version 3.2.

The **`QueueListener`** class, located in the **`logging.handlers`** module, supports receiving logging messages from a queue, such as those implemented in the **`queue`** or **`multiprocessing`** modules. The messages are received from a queue in an internal thread and passed, on the same thread, to one or more handlers for processing. While **`QueueListener`** is not itself a handler, it is documented here because it works hand-in-hand with **`QueueHandler`**.

Along with the **`QueueHandler`** class, **`QueueListener`** can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via **`SMTPHandler`**) are done on a separate thread.

class logging.handlers.QueueListener(*queue*, **handlers*, *respect_handler_level=False*)

Returns a new instance of the **`QueueListener`** class. The instance is initialized with the queue to send messages to and a list of handlers which will handle entries placed on the queue. The queue can be any queue-like object; it's passed as-is to the **`dequeue()`** method, which needs to know how to get messages from it. The queue is not *required* to have the task tracking API (though it's used if available), which means that you can use **`SimpleQueue`** instances for *queue*.

Note

If you are using **multiprocessing**, you should avoid using **SimpleQueue** and instead use **multiprocessing.Queue**.

If respect_handler_level is True, a handler's level is respected (compared with the level for the message) when deciding whether to pass messages to that handler; otherwise, the behaviour is as in previous Python versions - to always pass each message to each handler.

Changed in version 3.5: The respect_handler_level argument was added.

dequeue(*block*)

Dequeues a record and return it, optionally blocking.

The base implementation uses get(). You may want to override this method if you want to use timeouts or work with custom queue implementations.

prepare(*record*)

Prepare a record for handling.

This implementation just returns the passed-in record. You may want to override this method if you need to do any custom marshalling or manipulation of the record before passing it to the handlers.

handle(*record*)

Handle a record.

This just loops through the handlers offering them the record to handle. The actual object passed to the handlers is that which is returned from **prepare()**.

start()

Starts the listener.

This starts up a background thread to monitor the queue for LogRecords to process.

stop()

Stops the listener.

This asks the thread to terminate, and then waits for it to do so. Note that if you don't call this before your application exits, there may be some records still left on the queue, which won't be processed.

enqueue_sentinel()

Writes a sentinel to the queue to tell the listener to quit. This implementation uses `put_nowait()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

New in version 3.3.

`getpass` — Portable password input

Source code: Lib/getpass.py [https://github.com/python/cpython/tree/3.11/Lib/getpass.py]

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The `getpass` module provides two functions:

getpass.getpass(*prompt='Password: '*, *stream=None*)

Prompt the user for a password without echoing. The user is prompted using the string *prompt*, which defaults to `'Password: '`. On Unix, the prompt is written to the file-like object *stream* using the replace error handler if needed. *stream* defaults to the controlling terminal (`/dev/tty`) or if that is unavailable to `sys.stderr` (this argument is ignored on Windows).

If echo free input is unavailable getpass() falls back to printing a warning message to *stream* and reading from `sys.stdin` and issuing a `GetPassWarning`.

Note

If you call getpass from within IDLE, the input may be done in the terminal you launched IDLE from rather than the idle window itself.

exception getpass.GetPassWarning

A **`UserWarning`** subclass issued when password input may be echoed.

getpass.getuser()

Return the “login name” of the user.

This function checks the environment variables **`LOGNAME`**, **`USER`**, **`LNAME`** and **`USERNAME`**, in order, and returns the value of the first one which is set to a non-empty string. If none are set, the login name from the password database is returned on systems which support the **`pwd`** module, otherwise, an exception is raised.

In general, this function should be preferred over **`os.getlogin()`**.

`curses` — Terminal handling for character-cell displays

Source code: Lib/curses [https://github.com/python/cpython/tree/3.11/Lib/curses]

The `curses` module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for Windows, DOS, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

Note

Whenever the documentation mentions a *character* it can be specified as an integer, a one-character Unicode string or a one-byte byte string.

Whenever the documentation mentions a *character string* it can be specified as a Unicode string or a byte string.

Curses Programming with Python
Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

The Tools/demo/ [https://github.com/python/cpython/tree/3.11/Tools/demo/] directory in the Python source distribution contains some example programs using the curses bindings provided by this module.

Functions

The module `curses` defines the following exception:

exception curses.error
Exception raised when a curses library function returns an error.

Note

Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to `A_NORMAL`.

The module `curses` defines the following functions:

curses.baudrate()
Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

curses.beep()
Emit a short attention sound.

curses.can_change_color()

Return `True` or `False`, depending on whether the programmer can change the colors displayed by the terminal.

curses.cbreak()

Enter cbreak mode. In cbreak mode (sometimes called “rare” mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first **`raw()`** then **`cbreak()`** leaves the terminal in cbreak mode.

curses.color_content(*color_number*)

Return the intensity of the red, green, and blue (RGB) components in the color *color_number*, which must be between `0` and `COLORS - 1`. Return a 3-tuple, containing the R,G,B values for the given color, which will be between `0` (no component) and `1000` (maximum amount of component).

curses.color_pair(*pair_number*)

Return the attribute value for displaying text in the specified color pair. Only the first 256 color pairs are supported. This attribute value can be combined with **`A_STANDOUT`**, **`A_REVERSE`**, and the other **`A_*`** attributes. **`pair_number()`** is the counterpart to this function.

curses.curs_set(*visibility*)

Set the cursor state. *visibility* can be set to `0`, `1`, or `2`, for invisible, normal, or very visible. If the terminal supports the visibility requested, return the previous cursor state; otherwise raise an exception. On many terminals, the “visible” mode is an underline cursor and the “very visible” mode is a block cursor.

curses.def_prog_mode()

Save the current terminal mode as the “program” mode, the

mode when the running program is using curses. (Its counterpart is the “shell” mode, for when the program is not in curses.) Subsequent calls to **reset_prog_mode()** will restore this mode.

curses.def_shell_mode()

Save the current terminal mode as the “shell” mode, the mode when the running program is not using curses. (Its counterpart is the “program” mode, when the program is using curses capabilities.) Subsequent calls to **reset_shell_mode()** will restore this mode.

curses.delay_output(*ms*)

Insert an *ms* millisecond pause in output.

curses.doupdate()

Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The **doupdate()** ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a **noutrefresh()** call after write operations such as **addstr()** have been performed on a window. The normal **refresh()** call is simply **noutrefresh()** followed by **doupdate()**; if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing **noutrefresh()** calls on all windows, followed by a single **doupdate()**.

curses.echo()

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

curses.endwin()

De-initialize the library, and return terminal to normal status.

curses.erasechar()

Return the user's current erase character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses.filter()

The **filter()** routine, if used, must be called before **initscr()** is called. The effect is that, during those calls, **LINES** is set to `1`; the capabilities `clear`, `cup`, `cud`, `cud1`, `cuu1`, `cuu`, `vpa` are disabled; and the `home` string is set to the value of `cr`. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

curses.flash()

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as 'visible bell' to the audible attention signal produced by **beep()**.

curses.flushinp()

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

curses.getmouse()

After **getch()** returns **KEY_MOUSE** to signal a mouse event, this method should be called to retrieve the queued mouse event, represented as a 5-tuple `(id, x, y, z, bstate)`. *id* is an ID value used to distinguish multiple devices, and *x*, *y*, *z* are the event's coordinates. (*z* is currently unused.) *bstate* is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where *n* is the button number from 1 to 5: **BUTTONn_PRESSED**, **BUTTONn_RELEASED**,

BUTTONn_CLICKED, **BUTTONn_DOUBLE_CLICKED**, **BUTTONn_TRIPLE_CLICKED**, **BUTTON_SHIFT**, **BUTTON_CTRL**, **BUTTON_ALT**.

Changed in version 3.10: The `BUTTON5_*` constants are now exposed if they are provided by the underlying curses library.

curses.getsyx()

Return the current coordinates of the virtual screen cursor as a tuple `(y, x)`. If **leaveok** is currently `True`, then return `(-1, -1)`.

curses.getwin(*file*)

Read window related data stored in the file by an earlier **putwin()** call. The routine then creates and initializes a new window using that data, returning the new window object.

curses.has_colors()

Return `True` if the terminal can display colors; otherwise, return `False`.

curses.has_extended_color_support()

Return `True` if the module supports extended colors; otherwise, return `False`. Extended color support allows more than 256 color pairs for terminals that support more than 16 colors (e.g. xterm-256color).

Extended color support requires ncurses version 6.1 or later.

New in version 3.10.

curses.has_ic()

Return `True` if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

curses.has_il()

Return `True` if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

curses.has_key(*ch*)

Take a key value *ch*, and return `True` if the current terminal type recognizes a key with that value.

curses.halfdelay(*tenths*)

Used for half-delay mode, which is similar to cbreak mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, raise an exception if nothing has been typed. The value of *tenths* must be a number between `1` and `255`. Use **`nocbreak()`** to leave half-delay mode.

curses.init_color(*color_number*, *r*, *g*, *b*)

Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of *color_number* must be between `0` and `COLORS - 1`. Each of *r*, *g*, *b*, must be a value between `0` and `1000`. When **`init_color()`** is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if **`can_change_color()`** returns `True`.

curses.init_pair(*pair_number*, *fg*, *bg*)

Change the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair_number* must be between `1` and `COLOR_PAIRS - 1` (the `0` color pair is wired to white on black and cannot be changed). The value of *fg* and *bg* arguments must be between `0` and `COLORS - 1`, or, after

calling **`use_default_colors()`**, `-1`. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

curses.initscr()

Initialize the library. Return a window object which represents the whole screen.

Note

If there is an error opening the terminal, the underlying curses library may cause the interpreter to exit.

curses.is_term_resized(*nlines*, *ncols*)

Return `True` if **`resize_term()`** would modify the window structure, `False` otherwise.

curses.isendwin()

Return `True` if **`endwin()`** has been called (that is, the curses library has been deinitialized).

curses.keyname(*k*)

Return the name of the key numbered *k* as a bytes object. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-byte bytes object consisting of a caret (`b'^'`) followed by the corresponding printable ASCII character. The name of an alt-key combination (128–255) is a bytes object consisting of the prefix `b'M-'` followed by the name of the corresponding ASCII character.

curses.killchar()

Return the user's current line kill character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by

the curses library itself.

curses.longname()

Return a bytes object containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to `initscr()`.

curses.meta(*flag*)

If *flag* is `True`, allow 8-bit characters to be input. If *flag* is `False`, allow only 7-bit chars.

curses.mouseinterval(*interval*)

Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 milliseconds, or one fifth of a second.

curses.mousemask(*mousemask*)

Set the mouse events to be reported, and return a tuple `(availmask, oldmask)`. *availmask* indicates which of the specified mouse events can be reported; on complete failure it returns `0`. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

curses.napms(*ms*)

Sleep for *ms* milliseconds.

curses.newpad(*nlines*, *ncols*)

Create and return a pointer to a new pad data structure with the given number of lines and columns. Return a pad as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is

needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The **`refresh()`** and **`noutrefresh()`** methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

curses.newwin(*nlines*, *ncols*)

curses.newwin(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a new window, whose left-upper corner is at `(begin_y, begin_x)`, and whose height/width is *nlines*/*ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

curses.nl()

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

curses.nocbreak()

Leave cbreak mode. Return to normal “cooked” mode with line buffering.

curses.noecho()

Leave echo mode. Echoing of input characters is turned off.

curses.nonl()

Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch('\n')`, which always does the

equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

curses.noqiflush()

When the **noqiflush()** routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done. You may want to call **noqiflush()** in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

curses.noraw()

Leave raw mode. Return to normal "cooked" mode with line buffering.

curses.pair_content(*pair_number*)

Return a tuple `(fg, bg)` containing the colors for the requested color pair. The value of *pair_number* must be between `0` and `COLOR_PAIRS - 1`.

curses.pair_number(*attr*)

Return the number of the color-pair set by the attribute value *attr*. **color_pair()** is the counterpart to this function.

curses.putp(*str*)

Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of **putp()** always goes to standard output.

curses.qiflush([*flag*])

If *flag* is `False`, the effect is the same as calling **noqiflush()**. If *flag* is `True`, or no argument is provided, the queues will be flushed when these control characters are read.

curses.raw()

Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

curses.reset_prog_mode()

Restore the terminal to “program” mode, as previously saved by **def_prog_mode()**.

curses.reset_shell_mode()

Restore the terminal to “shell” mode, as previously saved by **def_shell_mode()**.

curses.resetty()

Restore the state of the terminal modes to what it was at the last call to **savetty()**.

curses.resize_term(*nlines*, *ncols*)

Backend function used by **resizeterm()**, performing most of the work; when resizing the windows, **resize_term()** blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The **resize_term()** function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

curses.resizeterm(*nlines*, *ncols*)

Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

curses.savetty()

Save the current state of the terminal modes in a buffer,

usable by **resetty()**.

curses.get_escdelay()

Retrieves the value set by **set_escdelay()**.

New in version 3.9.

curses.set_escdelay(*ms*)

Sets the number of milliseconds to wait after reading an escape character, to distinguish between an individual escape character entered on the keyboard from escape sequences sent by cursor and function keys.

New in version 3.9.

curses.get_tabsize()

Retrieves the value set by **set_tabsize()**.

New in version 3.9.

curses.set_tabsize(*size*)

Sets the number of columns used by the curses library when converting a tab character to spaces as it adds the tab to a window.

New in version 3.9.

curses.setsyx(*y*, *x*)

Set the virtual screen cursor to *y*, *x*. If *y* and *x* are both `-1`, then **leaveok** is set `True`.

curses.setupterm(*term=None*, *fd=-1*)

Initialize the terminal. *term* is a string giving the terminal name, or `None`; if omitted or `None`, the value of the **TERM** environment variable will be used. *fd* is the file descriptor to which any initialization sequences will be sent; if not supplied or `-1`, the file descriptor for `sys.stdout` will be used.

curses.start_color()

Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after **initscr()**.

start_color() initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the **curses** module, **COLORS** and **COLOR_PAIRS**, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

curses.termattrs()

Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

curses.termname()

Return the value of the environment variable **TERM**, as a bytes object, truncated to 14 characters.

curses.tigetflag(*capname*)

Return the value of the Boolean capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-1` if *capname* is not a Boolean capability, or `0` if it is canceled or absent from the terminal description.

curses.tigetnum(*capname*)

Return the value of the numeric capability corresponding to the terminfo capability name *capname* as an integer. Return the value `-2` if *capname* is not a numeric capability, or `-1` if it is canceled or absent from the terminal description.

curses.tigetstr(*capname*)

Return the value of the string capability corresponding to the terminfo capability name *capname* as a bytes object. Return

`None` if *capname* is not a terminfo “string capability”, or is canceled or absent from the terminal description.

curses.tparm(*str*[, ...])

Instantiate the bytes object *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `b'\033[6;4H'`, the exact result depending on terminal type.

curses.typeahead(*fd*)

Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is `-1`, then no typeahead checking is done.

The curses library does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until refresh or doupdate is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

curses.unctrl(*ch*)

Return a bytes object which is a printable representation of the character *ch*. Control characters are represented as a caret followed by the character, for example as `b'^C'`. Printing characters are left as they are.

curses.ungetch(*ch*)

Push *ch* so the next **`getch()`** will return it.

Note

Only one *ch* can be pushed before **`getch()`** is called.

curses.update_lines_cols()

Update **LINES** and **COLS**. Useful for detecting manual screen resize.

New in version 3.5.

curses.unget_wch(*ch*)

Push *ch* so the next **get_wch()** will return it.

Note

Only one *ch* can be pushed before **get_wch()** is called.

New in version 3.3.

curses.ungetmouse(*id*, *x*, *y*, *z*, *bstate*)

Push a **KEY_MOUSE** event onto the input queue, associating the given state data with it.

curses.use_env(*flag*)

If used, this function should be called before **initscr()** or newterm are called. When *flag* is `False`, the values of lines and columns specified in the terminfo database will be used, even if environment variables **LINES** and **COLUMNS** (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if **LINES** and **COLUMNS** are not set).

curses.use_default_colors()

Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number `-1`. After calling this function, `init_pair(x, curses.COLOR_RED, -1)` initializes, for instance, color pair *x* to a red foreground color on the default background.

curses.wrapper(*func*, */*, **args*, ***kwargs*)

Initialize curses and call another callable object, *func*, which

should be the rest of your curses-using application. If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window 'stdscr' as its first argument, followed by any other arguments passed to **wrapper()**. Before calling *func*, **wrapper()** turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

Window Objects

Window objects, as returned by **initscr()** and **newwin()** above, have the following methods and attributes:

window.addch(*ch*[, *attr*])
window.addch(*y*, *x*, *ch*[, *attr*])

Paint character *ch* at `(y, x)` with attributes *attr*, overwriting any character previously painted at that location. By default, the character position and attributes are the current settings for the window object.

Note

Writing outside the window, subwindow, or pad raises a **curses.error**. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

window.addnstr(*str*, *n*[, *attr*])
window.addnstr(*y*, *x*, *str*, *n*[, *attr*])

Paint at most *n* characters of the character string *str* at `(y, x)` with attributes *attr*, overwriting anything previously on the display.

window.addstr(*str*[, *attr*])

window.addstr(*y*, *x*, *str*[, *attr*])

Paint the character string *str* at `(y, x)` with attributes *attr*, overwriting anything previously on the display.

Note

- Writing outside the window, subwindow, or pad raises **`curses.error`**. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.
- A bug in ncurses [https://bugs.python.org/issue35924], the backend for this Python module, can cause SegFaults when resizing windows. This is fixed in ncurses-6.1-20190511. If you are stuck with an earlier ncurses, you can avoid triggering this if you do not call **`addstr()`** with a *str* that has embedded newlines. Instead, call **`addstr()`** separately for each line.

window.attroff(*attr*)

Remove attribute *attr* from the “background” set applied to all writes to the current window.

window.attron(*attr*)

Add attribute *attr* from the “background” set applied to all writes to the current window.

window.attrset(*attr*)

Set the “background” set of attributes to *attr*. This set is initially `0` (no attributes).

window.bkgd(*ch*[, *attr*])

Set the background property of the window to the character

ch, with attributes *attr*. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

window.bkgdset(*ch*[, *attr*])

Set the window's background. A window's background consists of a character and any combination of attributes. The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

window.border([*ls*[, *rs*[, *ts*[, *bs*[, *tl*[, *tr*[, *bl*[, *br*]]]]]]]])

Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details.

Note

A `0` value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table:

Parameter	Description	Default value
ls	Left side	ACS_VLINE
rs	Right side	ACS_VLINE
ts	Top	ACS_HLINE
bs	Bottom	ACS_HLINE
tl	Upper left-hand corner	ACS_ULCORNER
tr	Upper right-hand corner	ACS_URCORNER
bl	Bottom left-hand corner	ACS_LLCORNER
br	Bottom right-hand corner	ACS_LRCORNER

window.box([*vertch*, *horch*])

Similar to **`border()`**, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

window.chgat(*attr*)
window.chgat(*num*, *attr*)
window.chgat(*y*, *x*, *attr*)
window.chgat(*y*, *x*, *num*, *attr*)

Set the attributes of *num* characters at the current cursor position, or at position `(y, x)` if supplied. If *num* is not given or is `-1`, the attribute will be set on all the characters to the end of the line. This function moves cursor to position `(y, x)` if supplied. The changed line will be touched using the **`touchline()`** method so that the contents will be redisplayed by the next window refresh.

window.clear()

Like **`erase()`**, but also cause the whole window to be repainted upon next call to **`refresh()`**.

window.clearok(*flag*)

If *flag* is `True`, the next call to **`refresh()`** will clear the window completely.

window.clrtobot()

Erase from cursor to the end of the window: all lines below the cursor are deleted, and then the equivalent of **`clrtoeol()`** is performed.

window.clrtoeol()

Erase from cursor to the end of the line.

window.cursyncup()

Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

window.delch([*y*, *x*])

Delete any character at `(y, x)`.

window.deleteln()

Delete the line under the cursor. All following lines are moved up by one line.

window.derwin(*begin_y*, *begin_x*)
window.derwin(*nlines*, *ncols*, *begin_y*, *begin_x*)

An abbreviation for "derive window", **`derwin()`** is the same as calling **`subwin()`**, except that *begin_y* and *begin_x* are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

window.echochar(*ch*[, *attr*])

Add character *ch* with attribute *attr*, and immediately call **`refresh()`** on the window.

window.enclose(*y*, *x*)

Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning `True` or `False`. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

Changed in version 3.10: Previously it returned `1` or `0` instead of `True` or `False`.

window.encoding

Encoding used to encode method arguments (Unicode strings and characters). The encoding attribute is inherited from the parent window when a subwindow is created, for example with **`window.subwin()`**. By default, current locale encoding is used (see **`locale.getencoding()`**).

New in version 3.3.

window.erase()

Clear the window.

window.getbegyx()

Return a tuple `(y, x)` of co-ordinates of upper-left corner.

window.getbkgd()

Return the given window's current background character/attribute pair.

window.getch([*y*, *x*])

Get a character. Note that the integer returned does *not* have to be in ASCII range: function keys, keypad keys and so on are represented by numbers higher than 255. In no-delay mode, return `-1` if there is no input, otherwise wait until a key is pressed.

window.get_wch([*y*, *x*])

Get a wide character. Return a character for most keys, or an integer for function keys, keypad keys, and other special keys. In no-delay mode, raise an exception if there is no input.

New in version 3.3.

window.getkey([*y*, *x*])

Get a character, returning a string instead of an integer, as **`getch()`** does. Function keys, keypad keys and other special keys return a multibyte string containing the key name. In no-delay mode, raise an exception if there is no input.

window.getmaxyx()

Return a tuple `(y, x)` of the height and width of the window.

window.getparyx()

Return the beginning coordinates of this window relative to its parent window as a tuple `(y, x)`. Return `(-1, -1)` if this window has no parent.

window.getstr()
window.getstr(*n*)
window.getstr(*y*, *x*)
window.getstr(*y*, *x*, *n*)

Read a bytes object from the user, with primitive line editing capacity.

window.getyx()

Return a tuple `(y, x)` of current cursor position relative to the window's upper-left corner.

window.hline(*ch*, *n*)
window.hline(*y*, *x*, *ch*, *n*)

Display a horizontal line starting at `(y, x)` with length *n* consisting of the character *ch*.

window.idcok(*flag*)

If *flag* is `False`, curses no longer considers using the hardware insert/delete character feature of the terminal; if *flag* is `True`, use of character insertion and deletion is enabled. When curses is first initialized, use of character insert/delete is enabled by default.

window.idlok(*flag*)

If *flag* is `True`, **curses** will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

window.immedok(*flag*)

If *flag* is `True`, any change in the window image

automatically causes the window to be refreshed; you no longer have to call **`refresh()`** yourself. However, it may degrade performance considerably, due to repeated calls to wrefresh. This option is disabled by default.

window.inch([*y*, *x*])

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

window.insch(*ch*[, *attr*])

window.insch(*y*, *x*, *ch*[, *attr*])

Paint character *ch* at `(y, x)` with attributes *attr*, moving the line from position *x* right by one character.

window.insdelln(*nlines*)

Insert *nlines* lines into the specified window above the current line. The *nlines* bottom lines are lost. For negative *nlines*, delete *nlines* lines starting with the one under the cursor, and move the remaining lines up. The bottom *nlines* lines are cleared. The current cursor position remains the same.

window.insertln()

Insert a blank line under the cursor. All following lines are moved down by one line.

window.insnstr(*str*, *n*[, *attr*])

window.insnstr(*y*, *x*, *str*, *n*[, *attr*])

Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to *n* characters. If *n* is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

window.insstr(*str*[, *attr*])

window.insstr(*y*, *x*, *str*[, *attr*])

Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

window.instr([*n*])

window.instr(*y*, *x*[, *n*])

Return a bytes object of characters, extracted from the window starting at the current cursor position, or at *y*, *x* if specified. Attributes are stripped from the characters. If *n* is specified, **`instr()`** returns a string at most *n* characters long (exclusive of the trailing NUL).

window.is_linetouched(*line*)

Return `True` if the specified line was modified since the last call to **`refresh()`**; otherwise return `False`. Raise a **`curses.error`** exception if *line* is not valid for the given window.

window.is_wintouched()

Return `True` if the specified window was modified since the last call to **`refresh()`**; otherwise return `False`.

window.keypad(*flag*)

If *flag* is `True`, escape sequences generated by some keys (keypad, function keys) will be interpreted by **`curses`**. If *flag* is `False`, escape sequences will be left as is in the input stream.

window.leaveok(*flag*)

If *flag* is `True`, cursor is left where it is on update, instead of being at “cursor position.” This reduces cursor movement where possible. If possible the cursor will be made invisible.

If *flag* is `False`, cursor will always be at "cursor position" after an update.

window.move(*new_y*, *new_x*)

Move cursor to `(new_y, new_x)`.

window.mvderwin(*y*, *x*)

Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

window.mvwin(*new_y*, *new_x*)

Move the window so its upper-left corner is at `(new_y, new_x)`.

window.nodelay(*flag*)

If *flag* is `True`, **`getch()`** will be non-blocking.

window.notimeout(*flag*)

If *flag* is `True`, escape sequences will not be timed out.

If *flag* is `False`, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

window.noutrefresh()

Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call **`doupdate()`**.

window.overlay(*destwin*[, *sminrow*, *smincol*, *dminrow*, *dmincol*, *dmaxrow*, *dmaxcol*])

Overlay the window on top of *destwin*. The windows need not be the same size, only the overlapping region is copied. This

copy is non-destructive, which means that the current background character does not overwrite the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of **`overlay()`** can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

window.overwrite(*destwin*[, *sminrow*, *smincol*, *dminrow*, *dmincol*, *dmaxrow*, *dmaxcol*])

Overwrite the window on top of *destwin*. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of **`overwrite()`** can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

window.putwin(*file*)

Write all data associated with the window into the provided file object. This information can be later retrieved using the **`getwin()`** function.

window.redrawln(*beg*, *num*)

Indicate that the *num* screen lines, starting at line *beg*, are corrupted and should be completely redrawn on the next **`refresh()`** call.

window.redrawwin()

Touch the entire window, causing it to be completely redrawn on the next **`refresh()`** call.

window.refresh([*pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*,

smaxcol])

Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with **`newpad()`**. The additional parameters are needed to indicate what part of the pad and screen are involved. *pminrow* and *pmincol* specify the upper left-hand corner of the rectangle to be displayed in the pad. *sminrow*, *smincol*, *smaxrow*, and *smaxcol* specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

window.resize(*nlines*, *ncols*)

Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by **`bkgdset()`**) merged into them.

window.scroll([*lines*=*1*])

Scroll the screen or scrolling region upward by *lines* lines.

window.scrollok(*flag*)

Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is `False`, the cursor is left on the bottom line. If *flag* is `True`, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call **`idlok()`**.

window.setscrreg(*top*, *bottom*)

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

window.standend()

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

window.standout()

Turn on attribute *A_STANDOUT*.

window.subpad(*begin_y*, *begin_x*)
window.subpad(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a sub-window, whose upper-left corner is at `(begin_y, begin_x)`, and whose width/height is *ncols*/*nlines*.

window.subwin(*begin_y*, *begin_x*)
window.subwin(*nlines*, *ncols*, *begin_y*, *begin_x*)

Return a sub-window, whose upper-left corner is at `(begin_y, begin_x)`, and whose width/height is *ncols*/*nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

window.syncdown()

Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by **`refresh()`**, so it should almost never be necessary to call it manually.

window.syncok(*flag*)

If *flag* is `True`, then **`syncup()`** is called automatically whenever there is a change in the window.

window.syncup()

Touch all locations in ancestors of the window that have been changed in the window.

window.timeout(*delay*)

Set blocking or non-blocking read behavior for the window. If *delay* is negative, blocking read is used (which will wait indefinitely for input). If *delay* is zero, then non-blocking read is used, and `getch()` will return `-1` if no input is waiting. If *delay* is positive, then `getch()` will block for *delay* milliseconds, and return `-1` if there is still no input at the end of that time.

window.touchline(*start*, *count*[, *changed*])

Pretend *count* lines have been changed, starting with line *start*. If *changed* is supplied, it specifies whether the affected lines are marked as having been changed (*changed*=`True`) or unchanged (*changed*=`False`).

window.touchwin()

Pretend the whole window has been changed, for purposes of drawing optimizations.

window.untouchwin()

Mark all lines in the window as unchanged since the last call to `refresh()`.

window.vline(*ch*, *n*)
window.vline(*y*, *x*, *ch*, *n*)

Display a vertical line starting at `(y, x)` with length *n* consisting of the character *ch*.

Constants

The `curses` module defines the following data members:

curses.ERR

Some curses routines that return an integer, such as **getch()**, return **ERR** upon failure.

curses.OK

Some curses routines that return an integer, such as **napms()**, return **OK** upon success.

curses.version

A bytes object representing the current version of the module. Also available as **__version__**.

curses.ncurses_version

A named tuple containing the three components of the ncurses library version: *major*, *minor*, and *patch*. All values are integers. The components can also be accessed by name, so `curses.ncurses_version[0]` is equivalent to `curses.ncurses_version.major` and so on.

Availability: if the ncurses library is used.

New in version 3.8.

Some constants are available to specify character cell attributes. The exact constants available are system dependent.

Attribute	Meaning
A_ALTCHARSET	Alternate character set mode
A_BLINK	Blink mode
A_BOLD	Bold mode
A_DIM	Dim mode
A_INVIS	Invisible or blank mode
A_ITALIC	Italic mode
A_NORMAL	Normal attribute
A_PROTECT	Protected mode
A_REVERSE	Reverse background and foreground colors
A_STANDOUT	Standout mode
A_UNDERLINE	Underline mode
A_HORIZONTAL	Horizontal highlight

A_LEFT	Left highlight
A_LOW	Low highlight
A_RIGHT	Right highlight
A_TOP	Top highlight
A_VERTICAL	Vertical highlight
A_CHARTEXT	Bit-mask to extract a character

New in version 3.7: `A_ITALIC` was added.

Several constants are available to extract corresponding attributes returned by some methods.

Bit-mask	Meaning
A_ATTRIBUTES	Bit-mask to extract attributes
A_CHARTEXT	Bit-mask to extract a character
A_COLOR	Bit-mask to extract color-pair field information

Keys are referred to by integer constants with names starting with `KEY_`. The exact keycaps available are system dependent.

Key constant	
KEY_MIN	Minimum key value
KEY_BREAK	Break key (unreliable)
KEY_DOWN	Down-arrow
KEY_UP	Up-arrow
KEY_LEFT	Left-arrow
KEY_RIGHT	Right-arrow
KEY_HOME	Home key (upward + left arrow)
KEY_BACKSPACE	Backspace (unreliable)
KEY_F0	Function keys. Up to 64 function keys are supported.
KEY_F(*n*)	Value of function key *n*
KEY_DL	Delete line
KEY_IL	Insert line
KEY_DC	Delete character
KEY_IC	Insert char or enter insert mode
KEY_EIC	Exit insert char mode
KEY_CLEAR	Clear screen
KEY_EOS	Clear to end of screen
KEY_EOL	Clear to end of line
KEY_SF	Scroll 1 line forward
KEY_SR	Scroll 1 line backward (reverse)

Next_page	NEXT_PAGE
Previous page	PREV_PAGE
Set tab	SET_TAB
Clear tab	CLEAR_TAB
Clear all tabs	CLEAR_ALL_TABS
Enter or send	ENTER
Soft (partial) reset (unreliable)	SOFT_RESET
Reset or hard reset (unreliable)	RESET
Print	PRINT
Home down or bottom (lower left)	HOME_DOWN
Upper left of keypad	KP_A1
Upper right of keypad	KP_A3
Center of keypad	KP_B2
Lower left of keypad	KP_C1
Lower right of keypad	KP_C3
Back tab	BACK_TAB
Beg (beginning)	BEG

Terminal resize	Terminal resize event
Max_key	Maximum key value

On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (**KEY_F1**, **KEY_F2**, **KEY_F3**, **KEY_F4**) available, and the arrow keys mapped to **KEY_UP**, **KEY_DOWN**, **KEY_LEFT** and **KEY_RIGHT** in the obvious way. If your machine has a PC keyboard, it is safe to expect

arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following keypad mappings are standard:

Constant	Keypad
KEY_B1	upper left
KEY_B3	upper right
KEY_C1	lower left
KEY_C3	lower right
KEY_HOME	home
KEY_END	end
KEY_PPAGE	page up
KEY_NPAGE	page down

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

Note

These are available only after **`initscr()`** has been called.

ACS code	Meaning
ACS_BBSS	alternate name for upper right corner
ACS_BLOCK	solid square block
ACS_BOARD	board of squares
ACS_BSSB	alternate name for horizontal line
ACS_BSSS	alternate name for upper left corner
ACS_BTEE	alternate name for top tee
ACS_BULLET	bullet
ACS_CKBOARD	checker board (stipple)
ACS_DARROW	arrow pointing down
ACS_DEGREE	degree symbol
ACS_DIAMOND	diamond
ACS_GEQUAL	greater-than-or-equal-to
ACS_HLINE	horizontal line
ACS_LANTERN	lantern symbol
ACS_LARROW	left arrow
ACS_LEQUAL	less-than-or-equal-to

lower_left_hand	lower left-hand corner
lower_right_hand	lower right-hand corner
left_tee	left tee
not_equal	not-equal sign
letter_pi	letter pi
plus_or_minus	plus-or-minus sign
big_plus	big plus sign
right_arrow	right arrow
right_tee	right tee
scan_line_1	scan line 1
scan_line_3	scan line 3
scan_line_7	scan line 7
scan_line_9	scan line 9
alternate_lrcorner	alternate name for lower right corner
alternate_vline	alternate name for vertical line
alternate_rtee	alternate name for right tee
alternate_llcorner	alternate name for lower left corner
alternate_btee	alternate name for bottom tee
alternate_ltee	alternate name for left tee
alternate_plus	alternate name for crossover or big plus
pound_sterling	pound sterling
top_tee	top tee
up_arrow	up arrow
upper_left_corner	upper left-hand corner
upper_right_corner	upper right-hand corner
vertical_line	vertical line

The following table lists the predefined colors:

Color constant	
COLOR_BLACK	Black
COLOR_BLUE	Blue
COLOR_CYAN	Cyan (light greenish blue)
COLOR_GREEN	Green
COLOR_MAGENTA	Magenta (purplish red)
COLOR_RED	Red
COLOR_WHITE	White
COLOR_YELLOW	Yellow

`curses.textpad` — Text input widget for curses programs

The `curses.textpad` module provides a `Textbox` class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module `curses.textpad` defines the following function:

curses.textpad.rectangle(*win*, *uly*, *ulx*, *lry*, *lrx*)

> Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

Textbox objects

You can instantiate a `Textbox` object as follows:

class curses.textpad.Textbox(*win*)

> Return a textbox widget object. The *win* argument should be a curses window object in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates `(0, 0)`. The instance's `stripspaces` flag is initially on.
>
> `Textbox` objects have the following methods:

edit([*validator*])

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the **stripspaces** attribute.

do_command(*ch*)

Process a single command keystroke. Here are the supported special keystrokes:

Keystroke	Meaning
Control-A	Go to left edge of window.
Control-B	Cursor left, wrapping to previous line if appropriate.
Control-D	Delete character under cursor.
Control-E	Go to right edge (stripspaces off) or end of line (stripspaces on).
Control-F	Cursor right, wrapping to next line when appropriate.
Control-G	Terminate, returning the window contents.
Control-H	Delete character backward.
Control-J	Terminate if the window is 1 line, otherwise insert newline.
Control-K	If line is blank, delete it, otherwise clear to end of line.
Control-L	Refresh screen.
Control-N	Cursor down; move down one line.
Control-O	Insert a blank line at cursor location.
Control-P	Cursor up; move up one line.

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible:

Keystroke	Meaning
KEY_LEFT	Control-B

KEY_RIGHT
KEY_UP Ctrl-P
KEY_DOWN Ctrl-N
KEY_BACKSPACE

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather()

Return the window contents as a string; whether blanks in the window are included is affected by the **stripspaces** member.

stripspaces

This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

`curses.ascii` — Utilities for ASCII characters

Source code: Lib/curses/ascii.py [https://github.com/python/cpython/tree/3.11/Lib/curses/ascii.py]

The `curses.ascii` module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

Name	Meaning
`NUL`	
`SOH`	Start of heading, console interrupt
`STX`	Start of text
`ETX`	End of text
`EOT`	End of transmission
`ENQ`	Enquiry, goes with `ACK` flow control
`ACK`	Acknowledgement
`BEL`	
`BS`	Backspace
`TAB`	
`HT`	Alias for `TAB`: “Horizontal tab”
`LF`	Line feed
`NL`	Alias for `LF`: “New line”
`VT`	Vertical tab
`FF`	Form feed
`CR`	Carriage return
`SO`	Shift-out, begin alternate character set
`SI`	Shift-in, resume default character set
`DLE`	Data-link escape
`DC1`	XON, for flow control
`DC2`	Device control 2, block-mode flow control
`DC3`	XOFF, for flow control

DC4	Device control 4
NAK	Negative acknowledgement
SYN	Synchronous idle
ETB	End transmission block
CAN	Cancel
EM	End of medium
SUB	Substitute
ESC	Escape
FS	File separator
GS	Group separator
RS	Record separator, block-mode terminator
US	Unit separator
SP	Space
DEL	Delete

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

curses.ascii.isalnum(*c*)

Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c) or isdigit(c)`.

curses.ascii.isalpha(*c*)

Checks for an ASCII alphabetic character; it is equivalent to `isupper(c) or islower(c)`.

curses.ascii.isascii(*c*)

Checks for a character value that fits in the 7-bit ASCII set.

curses.ascii.isblank(*c*)

Checks for an ASCII whitespace character; space or horizontal tab.

curses.ascii.iscntrl(*c*)

Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

curses.ascii.isdigit(*c*)

Checks for an ASCII decimal digit, `'0'` through `'9'`. This is equivalent to `c in string.digits`.

curses.ascii.isgraph(*c*)

Checks for ASCII any printable character except space.

curses.ascii.islower(*c*)

Checks for an ASCII lower-case character.

curses.ascii.isprint(*c*)

Checks for any ASCII printable character including space.

curses.ascii.ispunct(*c*)

Checks for any printable ASCII character which is not a space or an alphanumeric character.

curses.ascii.isspace(*c*)

Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

curses.ascii.isupper(*c*)

Checks for an ASCII uppercase letter.

curses.ascii.isxdigit(*c*)

Checks for an ASCII hexadecimal digit. This is equivalent to `c in string.hexdigits`.

curses.ascii.isctrl(*c*)

Checks for an ASCII control character (ordinal values 0 to 31).

curses.ascii.ismeta(*c*)

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or single-character strings; when the argument is a string, it is first converted using the built-in function `ord()`.

Note that all these functions check ordinal bit values derived from the character of the string you pass in; they do not actually know anything about the host machine's character encoding.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

curses.ascii.ascii(*c*)

Return the ASCII value corresponding to the low 7 bits of *c*.

curses.ascii.ctrl(*c*)

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

curses.ascii.alt(*c*)

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

curses.ascii.unctrl(*c*)

Return a string representation of the ASCII character *c*. If *c* is printable, this string is the character itself. If the character is a control character (0x00–0x1f) the string consists of a caret (`'^'`) followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is `'^?'`. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and `'!'` prepended to the result.

curses.ascii.controlnames

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic `SP` for the space character.

`curses.panel` — A panel stack extension for curses

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

Functions

The module `curses.panel` defines the following functions:

curses.panel.bottom_panel()

Returns the bottom panel in the panel stack.

curses.panel.new_panel(*win*)

Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

curses.panel.top_panel()

Returns the top panel in the panel stack.

curses.panel.update_panels()

Updates the virtual screen after changes in the panel stack. This does not call `curses.doupdate()`, so you'll have to do this yourself.

Panel Objects

Panel objects, as returned by **`new_panel()`** above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

Panel.above()

Returns the panel above the current panel.

Panel.below()

Returns the panel below the current panel.

Panel.bottom()

Push the panel to the bottom of the stack.

Panel.hidden()

Returns `True` if the panel is hidden (not visible), `False` otherwise.

Panel.hide()

Hide the panel. This does not delete the object, it just makes the window on screen invisible.

Panel.move(*y*, *x*)

Move the panel to the screen coordinates `(y, x)`.

Panel.replace(*win*)

Change the window associated with the panel to the window *win*.

Panel.set_userptr(*obj*)

Set the panel's user pointer to *obj*. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

Panel.show()

Display the panel (which might have been hidden).

Panel.top()

Push panel to the top of the stack.

Panel.userptr()

Returns the user pointer for the panel. This might be any Python object.

Panel.window()

Returns the window object associated with the panel.

`platform` — Access to underlying platform's identifying data

Source code: Lib/platform.py [https://github.com/python/cpython/tree/3.11/Lib/platform.py]

Note

Specific platforms listed alphabetically, with Linux included in the Unix section.

Cross Platform

platform.architecture(*executable=sys.executable*, *bits=''*, *linkage=''*)

Queries the given executable (defaults to the Python interpreter binary) for various architecture information.

Returns a tuple `(bits, linkage)` which contain information about the bit architecture and the linkage format used for the executable. Both values are returned as strings.

Values that cannot be determined are returned as given by the parameter presets. If bits is given as `''`, the `sizeof(pointer)` (or `sizeof(long)` on Python version < 1.5.2) is used as indicator for the supported pointer size.

The function relies on the system's `file` command to do the actual work. This is available on most if not all Unix platforms and some non-Unix platforms and then only if the executable points to the Python interpreter. Reasonable defaults are used when the above needs are not met.

Note

On macOS (and perhaps other platforms), executable files may be universal files containing multiple architectures.

To get at the "64-bitness" of the current interpreter, it is more reliable to query the **sys.maxsize** attribute:

```
is_64bits = sys.maxsize > 2**32
```

platform.machine()

Returns the machine type, e.g. `'AMD64'`. An empty string is returned if the value cannot be determined.

platform.node()

Returns the computer's network name (may not be fully qualified!). An empty string is returned if the value cannot be determined.

platform.platform(*aliased=0*, *terse=0*)

Returns a single string identifying the underlying platform with as much useful information as possible.

The output is intended to be *human readable* rather than machine parseable. It may look different on different platforms and this is intended.

If *aliased* is true, the function will use aliases for various platforms that report system names which differ from their common names, for example SunOS will be reported as Solaris. The **system_alias()** function is used to implement this.

Setting *terse* to true causes the function to return only the absolute minimum information needed to identify the platform.

Changed in version 3.8: On macOS, the function now uses

mac_ver(), if it returns a non-empty release string, to get the macOS version rather than the darwin version.

platform.processor()

Returns the (real) processor name, e.g. `'amdk6'`.

An empty string is returned if the value cannot be determined. Note that many platforms do not provide this information or simply return the same value as for **machine()**. NetBSD does this.

platform.python_build()

Returns a tuple `(buildno, builddate)` stating the Python build number and date as strings.

platform.python_compiler()

Returns a string identifying the compiler used for compiling Python.

platform.python_branch()

Returns a string identifying the Python implementation SCM branch.

platform.python_implementation()

Returns a string identifying the Python implementation. Possible return values are: 'CPython', 'IronPython', 'Jython', 'PyPy'.

platform.python_revision()

Returns a string identifying the Python implementation SCM revision.

platform.python_version()

Returns the Python version as string `'major.minor.patchlevel'`.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to 0).

platform.python_version_tuple()

Returns the Python version as tuple `(major, minor, patchlevel)` of strings.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to `'0'`).

platform.release()

Returns the system's release, e.g. `'2.2.0'` or `'NT'`. An empty string is returned if the value cannot be determined.

platform.system()

Returns the system/OS name, such as `'Linux'`, `'Darwin'`, `'Java'`, `'Windows'`. An empty string is returned if the value cannot be determined.

platform.system_alias(*system*, *release*, *version*)

Returns `(system, release, version)` aliased to common marketing names used for some systems. It also does some reordering of the information in some cases where it would otherwise cause confusion.

platform.version()

Returns the system's release version, e.g. `'#3 on degas'`. An empty string is returned if the value cannot be determined.

platform.uname()

Fairly portable uname interface. Returns a **`namedtuple()`** containing six attributes: **`system`**, **`node`**, **`release`**, **`version`**, **`machine`**, and **`processor`**.

Note that this adds a sixth attribute (**`processor`**) not present in the **`os.uname()`** result. Also, the attribute names are

different for the first two attributes; `os.uname()` names them **sysname** and **nodename**.

Entries which cannot be determined are set to `''`.

Changed in version 3.3: Result changed from a tuple to a `namedtuple()`.

Java Platform

platform.java_ver(*release*='', *vendor*='', *vminfo*=('', '', ''), *osinfo*=('', '', ''))

Version interface for Jython.

Returns a tuple `(release, vendor, vminfo, osinfo)` with *vminfo* being a tuple `(vm_name, vm_release, vm_vendor)` and *osinfo* being a tuple `(os_name, os_version, os_arch)`. Values which cannot be determined are set to the defaults given as parameters (which all default to `''`).

Windows Platform

platform.win32_ver(*release*='', *version*='', *csd*='', *ptype*='')

Get additional version information from the Windows Registry and return a tuple `(release, version, csd, ptype)` referring to OS release, version number, CSD level (service pack) and OS type (multi/single processor). Values which cannot be determined are set to the defaults given as parameters (which all default to an empty string).

As a hint: *ptype* is `'Uniprocessor Free'` on single processor NT machines and `'Multiprocessor Free'` on multi processor machines. The *'Free'* refers to the OS version being free of debugging code. It could also state *'Checked'* which means the OS version uses debugging code, i.e. code that checks arguments, ranges, etc.

platform.win32_edition()

Returns a string representing the current Windows edition, or `None` if the value cannot be determined. Possible values include but are not limited to `'Enterprise'`, `'IoTUAP'`, `'ServerStandard'`, and `'nanoserver'`.

New in version 3.8.

platform.win32_is_iot()

Return `True` if the Windows edition returned by **`win32_edition()`** is recognized as an IoT edition.

New in version 3.8.

macOS Platform

platform.mac_ver(*release=''*, *versioninfo=('', '', '')*, *machine=''*)

Get macOS version information and return it as tuple `(release, versioninfo, machine)` with *versioninfo* being a tuple `(version, dev_stage, non_release_version)`.

Entries which cannot be determined are set to `''`. All tuple entries are strings.

Unix Platforms

platform.libc_ver(*executable=sys.executable*, *lib=''*, *version=''*, *chunksize=16384*)

Tries to determine the libc version against which the file executable (defaults to the Python interpreter) is linked. Returns a tuple of strings `(lib, version)` which default to the given parameters in case the lookup fails.

Note that this function has intimate knowledge of how different libc versions add symbols to the executable is probably only usable for executables compiled using **gcc**.

The file is read and scanned in chunks of *chunksize* bytes.

Linux Platforms

platform.freedesktop_os_release()

Get operating system identification from `os-release` file and return it as a dict. The `os-release` file is a freedesktop.org standard [https://www.freedesktop.org/software/systemd/man/os-release.html] and is available in most Linux distributions. A noticeable exception is Android and Android-based distributions.

Raises **`OSError`** or subclass when neither `/etc/os-release` nor `/usr/lib/os-release` can be read.

On success, the function returns a dictionary where keys and values are strings. Values have their special characters like `"` and `$` unquoted. The fields `NAME`, `ID`, and `PRETTY_NAME` are always defined according to the standard. All other fields are optional. Vendors may include additional fields.

Note that fields like `NAME`, `VERSION`, and `VARIANT` are strings suitable for presentation to users. Programs should use fields like `ID`, `ID_LIKE`, `VERSION_ID`, or `VARIANT_ID` to identify Linux distributions.

Example:

```
def get_like_distro():
    info = platform.freedesktop_os_release()
    ids = [info["ID"]]
    if "ID_LIKE" in info:
        # ids are space separated and ordered by pr
        ids.extend(info["ID_LIKE"].split())
    return ids
```

New in version 3.10.

`errno` — Standard errno system symbols

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be all-inclusive.

errno.errorcode

> Dictionary providing a mapping from the errno value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use **`os.strerror()`**.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

errno.EPERM

> Operation not permitted. This error is mapped to the exception **`PermissionError`**.

errno.ENOENT

> No such file or directory. This error is mapped to the exception **`FileNotFoundError`**.

errno.ESRCH

> No such process. This error is mapped to the exception **`ProcessLookupError`**.

errno.EINTR
: Interrupted system call. This error is mapped to the exception **`InterruptedError`**.

errno.EIO
: I/O error

errno.ENXIO
: No such device or address

errno.E2BIG
: Arg list too long

errno.ENOEXEC
: Exec format error

errno.EBADF
: Bad file number

errno.ECHILD
: No child processes. This error is mapped to the exception **`ChildProcessError`**.

errno.EAGAIN
: Try again. This error is mapped to the exception **`BlockingIOError`**.

errno.ENOMEM
: Out of memory

errno.EACCES
: Permission denied. This error is mapped to the exception **`PermissionError`**.

errno.EFAULT
: Bad address

errno.ENOTBLK
: Block device required

errno.EBUSY
: Device or resource busy

errno.EEXIST
: File exists. This error is mapped to the exception **`FileExistsError`**.

errno.EXDEV
: Cross-device link

errno.ENODEV
: No such device

errno.ENOTDIR
: Not a directory. This error is mapped to the exception **`NotADirectoryError`**.

errno.EISDIR
: Is a directory. This error is mapped to the exception **`IsADirectoryError`**.

errno.EINVAL
: Invalid argument

errno.ENFILE
: File table overflow

errno.EMFILE
: Too many open files

errno.ENOTTY
: Not a typewriter

errno.ETXTBSY
: Text file busy

errno.EFBIG
: File too large

errno.ENOSPC
: No space left on device

errno.ESPIPE
: Illegal seek

errno.EROFS
: Read-only file system

errno.EMLINK
: Too many links

errno.EPIPE
: Broken pipe. This error is mapped to the exception **`BrokenPipeError`**.

errno.EDOM
: Math argument out of domain of func

errno.ERANGE
: Math result not representable

errno.EDEADLK
: Resource deadlock would occur

errno.ENAMETOOLONG
: File name too long

errno.ENOLCK
: No record locks available

errno.ENOSYS
: Function not implemented

errno.ENOTEMPTY
: Directory not empty

errno.ELOOP
: Too many symbolic links encountered

errno.EWOULDBLOCK
: Operation would block. This error is mapped to the exception **`BlockingIOError`**.

errno.ENOMSG
: No message of desired type

errno.EIDRM
: Identifier removed

errno.ECHRNG
: Channel number out of range

errno.EL2NSYNC
: Level 2 not synchronized

errno.EL3HLT
: Level 3 halted

errno.EL3RST
: Level 3 reset

errno.ELNRNG
: Link number out of range

errno.EUNATCH
: Protocol driver not attached

errno.ENOCSI
: No CSI structure available

errno.EL2HLT
: Level 2 halted

errno.EBADE
: Invalid exchange

errno.EBADR
: Invalid request descriptor

errno.EXFULL
: Exchange full

errno.ENOANO
: No anode

errno.EBADRQC
: Invalid request code

errno.EBADSLT
: Invalid slot

errno.EDEADLOCK
: File locking deadlock error

errno.EBFONT
: Bad font file format

errno.ENOSTR
: Device not a stream

errno.ENODATA
: No data available

errno.ETIME
: Timer expired

errno.ENOSR
: Out of streams resources

errno.ENONET
: Machine is not on the network

errno.ENOPKG
: Package not installed

errno.EREMOTE
: Object is remote

errno.ENOLINK
: Link has been severed

errno.EADV
: Advertise error

errno.ESRMNT
: Srmount error

errno.ECOMM
: Communication error on send

errno.EPROTO
: Protocol error

errno.EMULTIHOP
: Multihop attempted

errno.EDOTDOT
: RFS specific error

errno.EBADMSG
: Not a data message

errno.EOVERFLOW
: Value too large for defined data type

errno.ENOTUNIQ
: Name not unique on network

errno.EBADFD
: File descriptor in bad state

errno.EREMCHG
: Remote address changed

errno.ELIBACC
: Can not access a needed shared library

errno.ELIBBAD
: Accessing a corrupted shared library

errno.ELIBSCN
: .lib section in a.out corrupted

errno.ELIBMAX
: Attempting to link in too many shared libraries

errno.ELIBEXEC
: Cannot exec a shared library directly

errno.EILSEQ
: Illegal byte sequence

errno.ERESTART
: Interrupted system call should be restarted

errno.ESTRPIPE
: Streams pipe error

errno.EUSERS
: Too many users

errno.ENOTSOCK
: Socket operation on non-socket

errno.EDESTADDRREQ
: Destination address required

errno.EMSGSIZE
: Message too long

errno.EPROTOTYPE
: Protocol wrong type for socket

errno.ENOPROTOOPT
: Protocol not available

errno.EPROTONOSUPPORT
: Protocol not supported

errno.ESOCKTNOSUPPORT
: Socket type not supported

errno.EOPNOTSUPP
: Operation not supported on transport endpoint

errno.EPFNOSUPPORT
: Protocol family not supported

errno.EAFNOSUPPORT
: Address family not supported by protocol

errno.EADDRINUSE
: Address already in use

errno.EADDRNOTAVAIL
: Cannot assign requested address

errno.ENETDOWN
: Network is down

errno.ENETUNREACH
: Network is unreachable

errno.ENETRESET
: Network dropped connection because of reset

errno.ECONNABORTED
: Software caused connection abort. This error is mapped to the exception **`ConnectionAbortedError`**.

errno.ECONNRESET
: Connection reset by peer. This error is mapped to the exception **`ConnectionResetError`**.

errno.ENOBUFS
: No buffer space available

errno.EISCONN
: Transport endpoint is already connected

errno.ENOTCONN
: Transport endpoint is not connected

errno.ESHUTDOWN
: Cannot send after transport endpoint shutdown. This error is mapped to the exception **`BrokenPipeError`**.

errno.ETOOMANYREFS

Too many references: cannot splice

errno.ETIMEDOUT

Connection timed out. This error is mapped to the exception **`TimeoutError`**.

errno.ECONNREFUSED

Connection refused. This error is mapped to the exception **`ConnectionRefusedError`**.

errno.EHOSTDOWN

Host is down

errno.EHOSTUNREACH

No route to host

errno.EALREADY

Operation already in progress. This error is mapped to the exception **`BlockingIOError`**.

errno.EINPROGRESS

Operation now in progress. This error is mapped to the exception **`BlockingIOError`**.

errno.ESTALE

Stale NFS file handle

errno.EUCLEAN

Structure needs cleaning

errno.ENOTNAM

Not a XENIX named type file

errno.ENAVAIL

No XENIX semaphores available

errno.EISNAM
: Is a named type file

errno.EREMOTEIO
: Remote I/O error

errno.EDQUOT
: Quota exceeded

errno.EQFULL
: Interface output queue is full

  New in version 3.11.

errno.ENOTCAPABLE
: Capabilities insufficient. This error is mapped to the exception **`PermissionError`**.

  Availability: WASI, FreeBSD

  New in version 3.11.1.

`ctypes` — A foreign function library for Python

Source code: Lib/ctypes [https://github.com/python/cpython/tree/3.11/Lib/ctypes]

`ctypes` is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.

ctypes tutorial

Note: The code samples in this tutorial use `doctest` to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or macOS, they contain doctest directives in comments.

Note: Some code samples reference the ctypes `c_int` type. On platforms where `sizeof(long) == sizeof(int)` it is an alias to `c_long`. So, you should not be confused if `c_long` is printed if you would expect `c_int` — they are actually the same type.

Loading dynamic link libraries

`ctypes` exports the *cdll*, and on Windows *windll* and *oledll* objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. *cdll* loads libraries which export functions using the standard `cdecl` calling convention, while *windll* libraries call functions using the `stdcall` calling convention. *oledll* also uses the `stdcall` calling convention, and assumes the functions return a Windows **`HRESULT`** error code. The error code is used to automatically raise

an **OSError** exception when the function call fails.

Changed in version 3.3: Windows errors used to raise **WindowsError**, which is now an alias of **OSError**.

Here are some examples for Windows. Note that `msvcrt` is the MS standard C library containing most standard C functions, and uses the cdecl calling convention:

```
>>> from ctypes import *
>>> print(windll.kernel32)
<WinDLL 'kernel32', handle ... at ...>
>>> print(cdll.msvcrt)
<CDLL 'msvcrt', handle ... at ...>
>>> libc = cdll.msvcrt
>>>
```

Windows appends the usual `.dll` file suffix automatically.

Note

Accessing the standard C library through `cdll.msvcrt` will use an outdated version of the library that may be incompatible with the one being used by Python. Where possible, use native Python functionality, or else import and use the `msvcrt` module.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access can not be used to load libraries. Either the **LoadLibrary()** method of the dll loaders should be used, or you should load the library by creating an instance of CDLL by calling the constructor:

```
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>>
```

Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects:

```
>>> from ctypes import *
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.GetModuleHandleA)
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.MyOwnFunction)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
>>>
```

Note that win32 system dlls like `kernel32` and `user32` often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with an `W` appended to the name, while the ANSI version is exported with an `A` appended to the name. The win32 `GetModuleHandle` function, which returns a *module handle* for a given module name, has the following C prototype, and a macro is used to expose one of them as `GetModuleHandle` depending on whether UNICODE is defined or not:

```
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

windll does not try to select one of them by magic, you must access the version you need by specifying `GetModuleHandleA` or `GetModuleHandleW` explicitly, and then call it with bytes or string objects respectively.

Sometimes, dlls export functions with names which aren't valid Python identifiers, like `"??2@YAPAXI@Z"`. In this case you have to use **`getattr()`** to retrieve the function:

```
>>> getattr(cdll.msvcrt, "??2@YAPAXI@Z")
```

```
<_FuncPtr object at 0x...>
>>>
```

On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number:

```
>>> cdll.kernel32[1]
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
>>>
```

Calling functions

You can call these functions like any other Python callable. This example uses the `time()` function, which returns system time in seconds since the Unix epoch, and the `GetModuleHandleA()` function, which returns a win32 module handle.

This example calls both functions with a `NULL` pointer (`None` should be used as the `NULL` pointer):

```
>>> print(libc.time(None))
1150640792
>>> print(hex(windll.kernel32.GetModuleHandleA(None)))
0x1d000000
>>>
```

`ValueError` is raised when you call an `stdcall` function with the `cdecl` calling convention, or vice versa:

```
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough ar
```

```
>>>

>>> windll.msvcrt.printf(b"spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many argu
>>>
```

To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, **ctypes** uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values:

```
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
OSError: exception: access violation reading 0x00000020
>>>
```

There are, however, enough ways to crash Python with **ctypes**, so you should be careful anyway. The **faulthandler** module can be helpful in debugging crashes (e.g. from segmentation faults produced by erroneous C library calls).

`None`, integers, bytes objects and (unicode) strings are the only native Python objects that can directly be used as parameters in these function calls. `None` is passed as a C `NULL` pointer, bytes objects and strings are passed as pointer to the memory block that contains their data (char* or wchar_t*). Python integers are passed as the platforms default C int type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about **ctypes** data types.

Fundamental data types

`ctypes` defines a number of primitive C compatible data types:

ctypes type	C type	Python type
`c_bool`	_Bool	bool (1)
`c_char`	char	1-character bytes object
`c_wchar`	wchar_t	1-character string
`c_byte`	char	int
`c_ubyte`	unsigned char	int
`c_short`	short	int
`c_ushort`	unsigned short	int
`c_int`	int	int
`c_uint`	unsigned int	int
`c_long`	long	int
`c_ulong`	unsigned long	int
`c_longlong`	__int64 or long long	int
`c_ulonglong`	unsigned __int64 or unsigned long long	int
`c_size_t`	size_t	int
`c_ssize_t`	ssize_t or Py_ssize_t	int
`c_float`	float	float
`c_double`	double	float
`c_longdouble`	long double	float
`c_char_p`	char* (NUL terminated)	bytes object or None
`c_wchar_p`	wchar_t* (NUL terminated)	string or None
`c_void_p`	void*	int or None

1. The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value:

```
>>> c_int()
c_long(0)
>>> c_wchar_p("Hello, World")
c_wchar_p(140018365411392)
>>> c_ushort(-3)
c_ushort(65533)
>>>
```

Since these types are mutable, their value can also be changed afterwards:

```
>>> i = c_int(42)
>>> print(i)
c_long(42)
>>> print(i.value)
42
>>> i.value = -99
>>> print(i.value)
-99
>>>
```

Assigning a new value to instances of the pointer types **c_char_p**, **c_wchar_p**, and **c_void_p** changes the *memory location* they point to, *not the contents* of the memory block (of course not, because Python bytes objects are immutable):

```
>>> s = "Hello, World"
>>> c_s = c_wchar_p(s)
>>> print(c_s)
c_wchar_p(139966785747344)
>>> print(c_s.value)
Hello World
>>> c_s.value = "Hi, there"
>>> print(c_s)                # the memory location has ch
c_wchar_p(139966783348904)
>>> print(c_s.value)
Hi, there
>>> print(s)                  # first object is unchanged
Hello, World
>>>
```

You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory blocks, ctypes has a **create_string_buffer()** function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property:

```
>>> from ctypes import *
>>> p = create_string_buffer(3)            # create a 3
```

```
>>> print(sizeof(p), repr(p.raw))
3 b'\x00\x00\x00'
>>> p = create_string_buffer(b"Hello")      # create a bu
>>> print(sizeof(p), repr(p.raw))
6 b'Hello\x00'
>>> print(repr(p.value))
b'Hello'
>>> p = create_string_buffer(b"Hello", 10) # create a 10
>>> print(sizeof(p), repr(p.raw))
10 b'Hello\x00\x00\x00\x00\x00'
>>> p.value = b"Hi"
>>> print(sizeof(p), repr(p.raw))
10 b'Hi\x00lo\x00\x00\x00\x00\x00'
>>>
```

The **`create_string_buffer()`** function replaces the old **`c_buffer()`** function (which is still available as an alias). To create a mutable memory block containing unicode characters of the C type wchar_t, use the **`create_unicode_buffer()`** function.

Calling functions, continued

Note that printf prints to the real standard output channel, *not* to **`sys.stdout`**, so these examples will only work at the console prompt, not from within *IDLE* or *PythonWin*:

```
>>> printf = libc.printf
>>> printf(b"Hello, %s\n", b"World!")
Hello, World!
14
>>> printf(b"Hello, %S\n", "World!")
Hello, World!
14
>>> printf(b"%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf(b"%f bottles of beer\n", 42.5)
Traceback (most recent call last):
```

```
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: TypeError: Don't know how to
>>>
```

As has been mentioned before, all Python types except integers, strings, and bytes objects have to be wrapped in their corresponding **ctypes** type, so that they can be converted to the required C data type:

```
>>> printf(b"An int %d, a double %f\n", 1234, c_double(3
An int 1234, a double 3.140000
31
>>>
```

Calling varadic functions

On a lot of platforms calling variadic functions through ctypes is exactly the same as calling functions with a fixed number of parameters. On some platforms, and in particular ARM64 for Apple Platforms, the calling convention for variadic functions is different than that for regular functions.

On those platforms it is required to specify the *argtypes* attribute for the regular, non-variadic, function arguments:

```
libc.printf.argtypes = [ctypes.c_char_p]
```

Because specifying the attribute does inhibit portability it is adviced to always specify `argtypes` for all variadic functions.

Calling functions with your own custom data types

You can also customize **ctypes** argument conversion to allow instances of your own classes be used as function arguments. **ctypes** looks for an **_as_parameter_** attribute and uses this as the function argument. Of course, it must be one of integer, string, or bytes:

```
>>> class Bottles:
...     def __init__(self, number):
```

```
...         self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf(b"%d bottles of beer\n", bottles)
42 bottles of beer
19
>>>
```

If you don't want to store the instance's data in the **_as_parameter_** instance variable, you could define a **property** which makes the attribute available on request.

Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the **argtypes** attribute.

argtypes must be a sequence of C data types (the `printf` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_doub
>>> printf(b"String '%s', Int %d, Double %f\n", b"Hi", 1
String 'Hi', Int 10, Double 2.200000
37
>>>
```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```
>>> printf(b"%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: TypeError: wrong type
>>> printf(b"%s %d %f\n", b"X", 2, 3)
X 2 3.000000
```

```
13
>>>
```

If you have defined your own classes which you pass to function calls, you have to implement a **`from_param()`** class method for them to be able to use them in the **`argtypes`** sequence. The **`from_param()`** class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its **`_as_parameter_`** attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, bytes, a **`ctypes`** instance, or an object with an **`_as_parameter_`** attribute.

Return types

By default functions are assumed to return the C int type. Other return types can be specified by setting the **`restype`** attribute of the function object.

Here is a more advanced example, it uses the `strchr` function, which expects a string pointer and a char, and returns a pointer to a string:

```
>>> strchr = libc.strchr
>>> strchr(b"abcdef", ord("d"))
8059983
>>> strchr.restype = c_char_p    # c_char_p is a pointer
>>> strchr(b"abcdef", ord("d"))
b'def'
>>> print(strchr(b"abcdef", ord("x")))
None
>>>
```

If you want to avoid the `ord("x")` calls above, you can set the **`argtypes`** attribute, and the second argument will be converted from a single character Python bytes object into a C char:

```
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
```

```
>>> strchr(b"abcdef", b"d")
'def'
>>> strchr(b"abcdef", b"def")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: TypeError: one character stri
>>> print(strchr(b"abcdef", b"x"))
None
>>> strchr(b"abcdef", b"d")
'def'
>>>
```

You can also use a callable Python object (a function or a class for example) as the **`restype`** attribute, if the foreign function returns an integer. The callable will be called with the *integer* the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception:

```
>>> GetModuleHandle = windll.kernel32.GetModuleHandleA
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
...
>>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in ValidHandle
OSError: [Errno 126] The specified module could not be f
>>>
```

`WinError` is a function which will call Windows `FormatMessage()` api to get the string representation of an error code, and *returns* an exception. `WinError` takes an optional error

code parameter, if no one is used, it calls **GetLastError()** to retrieve it.

Please note that a much more powerful error checking mechanism is available through the **errcheck** attribute; see the reference manual for details.

Passing pointers (or: passing parameters by reference)

Sometimes a C api function expects a *pointer* to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as *passing parameters by reference*.

ctypes exports the **byref()** function which is used to pass parameters by reference. The same effect can be achieved with the **pointer()** function, although **pointer()** does a lot more work since it constructs a real pointer object, so it is faster to use **byref()** if you don't need the pointer object in Python itself:

```
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer(b'\000' * 32)
>>> print(i.value, f.value, repr(s.value))
0 0.0 b''
>>> libc.sscanf(b"1 3.14 Hello", b"%d %f %s",
...             byref(i), byref(f), s)
3
>>> print(i.value, f.value, repr(s.value))
1 3.1400001049 b'Hello'
>>>
```

Structures and unions

Structures and unions must derive from the **Structure** and **Union** base classes which are defined in the **ctypes** module. Each subclass must define a **_fields_** attribute. **_fields_** must be a list of *2-tuples*, containing a *field name* and a *field type*.

The field type must be a **ctypes** type like **c_int**, or any other

derived **ctypes** type: structure, union, array, pointer.

Here is a simple example of a POINT structure, which contains two integers named *x* and *y*, and also shows how to initialize a structure in the constructor:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),
...                 ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print(point.x, point.y)
10 20
>>> point = POINT(y=5)
>>> print(point.x, point.y)
0 5
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: too many initializers
>>>
```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named *upperleft* and *lowerright*:

```
>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                 ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print(rc.upperleft.x, rc.upperleft.y)
0 5
>>> print(rc.lowerright.x, rc.lowerright.y)
0 0
>>>
```

Nested structures can also be initialized in the constructor in several ways:

```
>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))
```

Field descriptors can be retrieved from the *class*, they are useful for debugging because they can provide useful information:

```
>>> print(POINT.x)
<Field type=c_long, ofs=0, size=4>
>>> print(POINT.y)
<Field type=c_long, ofs=4, size=4>
>>>
```

Warning

ctypes does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior by specifying a **_pack_** class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

ctypes uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the **BigEndianStructure**, **LittleEndianStructure**, **BigEndianUnion**, and **LittleEndianUnion** base classes. These classes cannot contain pointer fields.

Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the **`_fields_`** tuples:

```
>>> class Int(Structure):
...     _fields_ = [("first_16", c_int, 16),
...                 ("second_16", c_int, 16)]
...
>>> print(Int.first_16)
<Field type=c_long, ofs=0:0, bits=16>
>>> print(Int.second_16)
<Field type=c_long, ofs=0:16, bits=16>
>>>
```

Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

```
TenPointsArrayType = POINT * 10
```

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]
>>>
>>> print(len(MyStruct().point_array))
4
>>>
```

Instances are created in the usual way, by calling the class:

```
arr = TenPointsArrayType()
for pt in arr:
    print(pt.x, pt.y)
```

The above code print a series of `0 0` lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print(ii)
<c_long_Array_10 object at 0x...>
>>> for i in ii: print(i, end=" ")
...
1 2 3 4 5 6 7 8 9 10
>>>
```

Pointers

Pointer instances are created by calling the **`pointer()`** function on a **`ctypes`** type:

```
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
>>>
```

Pointer instances have a **`contents`** attribute which returns the object to which the pointer points, the `i` object above:

```
>>> pi.contents
c_long(42)
>>>
```

Note that **`ctypes`** does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an

attribute:

```
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
>>>
```

Assigning another **`c_int`** instance to the pointer's contents attribute would cause the pointer to point to the memory location where this is stored:

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
>>>
```

Pointer instances can also be indexed with integers:

```
>>> pi[0]
99
>>>
```

Assigning to an integer index changes the pointed to value:

```
>>> print(i)
c_long(99)
>>> pi[0] = 22
>>> print(i)
c_long(22)
>>>
```

It is also possible to use indexes different from 0, but you must know what you're doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you *know* that the pointer actually points to an array instead of a single item.

Behind the scenes, the **`pointer()`** function does more than simply create pointer instances, it has to create pointer *types* first. This is

done with the **`POINTER()`** function, which accepts any **`ctypes`** type, and returns a new type:

```
>>> PI = POINTER(c_int)
>>> PI
<class 'ctypes.LP_c_long'>
>>> PI(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: expected c_long instead of int
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
>>>
```

Calling the pointer type without an argument creates a `NULL` pointer. `NULL` pointers have a `False` boolean value:

```
>>> null_ptr = POINTER(c_int)()
>>> print(bool(null_ptr))
False
>>>
```

`ctypes` checks for `NULL` when dereferencing pointers (but dereferencing invalid non-`NULL` pointers would crash Python):

```
>>> null_ptr[0]
Traceback (most recent call last):
    ....
ValueError: NULL pointer access
>>>

>>> null_ptr[0] = 1234
Traceback (most recent call last):
    ....
ValueError: NULL pointer access
>>>
```

Type conversions

Usually, ctypes does strict type checking. This means, if you have

`POINTER(c_int)` in the **`argtypes`** list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where ctypes accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, ctypes accepts an array of c_int:

```
>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print(bar.values[i])
...
1
2
3
>>>
```

In addition, if a function argument is explicitly declared to be a pointer type (such as `POINTER(c_int)`) in **`argtypes`**, an object of the pointed type (`c_int` in this case) can be passed to the function. ctypes will apply the required **`byref()`** conversion in this case automatically.

To set a POINTER type field to `NULL`, you can assign `None`:

```
>>> bar.values = None
>>>
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. **`ctypes`** provides a **`cast()`** function which can be used in the same way. The `Bar` structure defined above accepts `POINTER(c_int)` pointers or **`c_int`** arrays for its `values` field, but not instances of other types:

```
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
```

```
  File "<stdin>", line 1, in <module>
TypeError: incompatible types, c_byte_Array_4 instance i
>>>
```

For these cases, the **`cast()`** function is handy.

The **`cast()`** function can be used to cast a ctypes instance into a pointer to a different ctypes data type. **`cast()`** takes two parameters, a ctypes object that is or can be converted to a pointer of some kind, and a ctypes pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

```
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
>>>
```

So, **`cast()`** can be used to assign to the `values` field of `Bar` the structure:

```
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print(bar.values[0])
0
>>>
```

Incomplete Types

Incomplete Types are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later:

```
struct cell; /* forward declaration */

struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into ctypes code would be this, but it does not work:

```
>>> class cell(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("next", POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
NameError: name 'cell' is not defined
>>>
```

because the new `class cell` is not available in the class statement itself. In **ctypes**, we can define the `cell` class and set the **_fields_** attribute later, after the class statement:

```
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [("name", c_char_p),
...                  ("next", POINTER(cell))]
>>>
```

Let's try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```
>>> c1 = cell()
>>> c1.name = b"foo"
>>> c2 = cell()
>>> c2.name = b"bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print(p.name, end=" ")
...     p = p.next[0]
...
foo bar foo bar foo bar foo bar
```

```
>>>
```

Callback functions

ctypes allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function. The class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The **CFUNCTYPE()** factory function creates types for callback functions using the `cdecl` calling convention. On Windows, the **WINFUNCTYPE()** factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's **qsort()** function, that is used to sort items with the help of a callback function. **qsort()** will be used to sort an array of integers:

```
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
>>>
```

qsort() must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer otherwise.

So our callback function receives pointers to integers, and must return an integer. First we create the `type` for the callback function:

```
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c
>>>
```

To get started, here is a simple callback that shows the values it gets passed:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

The result:

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 5 7
py_cmp_func 1 7
>>>
```

Now we can actually compare the two items and return a useful result:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>>
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_fun
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

As we can easily check, our array is sorted now:

```
>>> for i in ia: print(i, end=" ")
...
1 5 7 33 99
>>>
```

The function factories can be used as decorator factories, so we may as well write:

```
>>> @CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
... def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>> qsort(ia, len(ia), sizeof(c_int), py_cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

Note

Make sure you keep references to **`CFUNCTYPE()`** objects as long as they are used from C code. **`ctypes`** doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), ctypes creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with **`threading.local`** will *not* survive across different callbacks, even when those calls are made from the same C thread.

Accessing values exported from dlls

Some shared libraries not only export functions, they also export

variables. An example in the Python library itself is the **Py_OptimizeFlag**, an integer set to 0, 1, or 2, depending on the **-O** or **-OO** flag given on startup.

ctypes can access values like this with the **in_dll()** class methods of the type. *pythonapi* is a predefined symbol giving access to the Python C api:

```
>>> opt_flag = c_int.in_dll(pythonapi, "Py_OptimizeFlag"
>>> print(opt_flag)
c_long(0)
>>>
```

If the interpreter would have been started with **-O**, the sample would have printed `c_long(1)`, or `c_long(2)` if **-OO** would have been specified.

An extended example which also demonstrates the use of pointers accesses the **PyImport_FrozenModules** pointer exported by Python.

Quoting the docs for that value:

> This pointer is initialized to point to an array of **_frozen** records, terminated by one whose members are all `NULL` or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with **ctypes**:

```
>>> from ctypes import *
>>>
>>> class struct_frozen(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("code", POINTER(c_ubyte)),
...                 ("size", c_int),
```

```
...                  ("get_code", POINTER(c_ubyte)),   # F
...                ]
...
>>>
```

We have defined the **_frozen** data type, so we can get the pointer to the table:

```
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "_PyImport_Fro
>>>
```

Since `table` is a `pointer` to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the `NULL` entry:

```
>>> for item in table:
...     if item.name is None:
...         break
...     print(item.name.decode("ascii"), item.size)
...
_frozen_importlib 31764
_frozen_importlib_external 41499
zipimport 12345
>>>
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative `size` member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

Surprises

There are some edges in **ctypes** where you might expect something other than what actually happens.

Consider the following example:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
...     _fields_ = ("a", POINT), ("b", POINT)
...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
>>> rc = RECT(p1, p2)
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
1 2 3 4
>>> # now swap the two points
>>> rc.a, rc.b = rc.b, rc.a
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
3 4 3 4
>>>
```

Hm. We certainly expected the last statement to print `3 4 1 2`. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```
>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>>
```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc` 's buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn't have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn't *copy* the sub-object, instead it retrieves a wrapper object accessing the root-object's underlying buffer.

Another example that may behave differently from what one would expect is this:

```
>>> s = c_char_p()
>>> s.value = b"abc def ghi"
>>> s.value
b'abc def ghi'
>>> s.value is s.value
False
>>>
```

Note

Objects instantiated from **`c_char_p`** can only have their value set to bytes or integers.

Why is it printing `False`? ctypes instances are objects containing a memory block plus some descriptors accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the `contents` of the object is stored. Accessing the contents again constructs a new Python object each time!

Variable-sized data types

`ctypes` provides some support for variable-sized arrays and structures.

The **`resize()`** function can be used to resize the memory buffer of an existing ctypes object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the objects type, a **`ValueError`** is raised if this is tried:

```
>>> short_array = (c_short * 4)()
>>> print(sizeof(short_array))
8
>>> resize(short_array, 4)
Traceback (most recent call last):
    ...
ValueError: minimum size is 8
```

```
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>>
```

This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```
>>> short_array[:]
[0, 0, 0, 0]
>>> short_array[7]
Traceback (most recent call last):
    ...
IndexError: invalid index
>>>
```

Another way to use variable-sized data types with **ctypes** is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.

ctypes reference

Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the **find_library()** function is to locate a library in a way similar to what the compiler or runtime loader does (on platforms with several versions of a shared library the most recent should be loaded), while the ctypes library loaders act like when a program is run, and call the runtime loader directly.

The **ctypes.util** module provides a function which can help to determine the library to load.

ctypes.util.find_library(*name*)

Try to find a library and return a pathname. *name* is the library name without any prefix like *lib*, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option **`-l`**). If no library can be found, returns `None`.

The exact functionality is system dependent.

On Linux, **`find_library()`** tries to run external programs (`/sbin/ldconfig`, `gcc`, `objdump` and `ld`) to find the library file. It returns the filename of the library file.

Changed in version 3.6: On Linux, the value of the environment variable `LD_LIBRARY_PATH` is used when searching for libraries, if a library cannot be found by any other means.

Here are some examples:

```
>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
>>> find_library("bz2")
'libbz2.so.1.0'
>>>
```

On macOS, **`find_library()`** tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful:

```
>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
```

```
>>>
```

On Windows, **`find_library()`** searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with **`ctypes`**, it *may* be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using **`find_library()`** to locate the library at runtime.

Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes:

class ctypes.CDLL(*name*, *mode=DEFAULT_MODE*, *handle=None*, *use_errno=False*, *use_last_error=False*, *winmode=None*)

Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return int.

On Windows creating a **`CDLL`** instance may fail even if the DLL name exists. When a dependent DLL of the loaded DLL is not found, a **`OSError`** error is raised with the message *"[WinError 126] The specified module could not be found"*. This error message does not contain the name of the missing DLL because the Windows API does not return this information making this error hard to diagnose. To resolve this error and determine which DLL is not found, you need to find the list of dependent DLLs and determine which one is not found using Windows debugging and tracing tools.

See also

Microsoft DUMPBIN tool [https://docs.microsoft.com/cpp/build/reference/dependents] – A tool to find DLL dependents.

class ctypes.OleDLL(*name*, *mode*=*DEFAULT_MODE*, *handle*=*None*, *use_errno*=*False*, *use_last_error*=*False*, *winmode*=*None*)

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return the windows specific **`HRESULT`** code. **`HRESULT`** values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an **`OSError`** is automatically raised.

Changed in version 3.3: **`WindowsError`** used to be raised.

class ctypes.WinDLL(*name*, *mode*=*DEFAULT_MODE*, *handle*=*None*, *use_errno*=*False*, *use_last_error*=*False*, *winmode*=*None*)

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return int by default.

The Python global interpreter lock is released before calling any function exported by these libraries, and reacquired afterwards.

class ctypes.PyDLL(*name*, *mode*=*DEFAULT_MODE*, *handle*=*None*)

Instances of this class behave like **`CDLL`** instances, except that the Python GIL is *not* released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the `handle` named parameter, otherwise the underlying platforms `dlopen` or `LoadLibrary` function is used to load the library into the process, and to get a handle to it.

The *mode* parameter can be used to specify how the library is loaded. For details, consult the *dlopen(3)* manpage. On Windows,

mode is ignored. On posix systems, RTLD_NOW is always added, and is not configurable.

The *use_errno* parameter, when set to true, enables a ctypes mechanism that allows accessing the system **errno** error number in a safe way. **ctypes** maintains a thread-local copy of the systems **errno** variable; if you call foreign functions created with `use_errno=True` then the **errno** value before the function call is swapped with the ctypes private copy, the same happens immediately after the function call.

The function **ctypes.get_errno()** returns the value of the ctypes private copy, and the function **ctypes.set_errno()** changes the ctypes private copy to a new value and returns the former value.

The *use_last_error* parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the **GetLastError()** and **SetLastError()** Windows API functions; **ctypes.get_last_error()** and **ctypes.set_last_error()** are used to request and change the ctypes private copy of the windows error code.

The *winmode* parameter is used on Windows to specify how the library is loaded (since *mode* is ignored). It takes any value that is valid for the Win32 API `LoadLibraryEx` flags parameter. When omitted, the default is to use the flags that result in the most secure DLL load to avoiding issues such as DLL hijacking. Passing the full path to the DLL is the safest way to ensure the correct library and dependencies are loaded.

Changed in version 3.8: Added *winmode* parameter.

ctypes.RTLD_GLOBAL

Flag to use as *mode* parameter. On platforms where this flag is not available, it is defined as the integer zero.

ctypes.RTLD_LOCAL

Flag to use as *mode* parameter. On platforms where this is not available, it is the same as *RTLD_GLOBAL*.

ctypes.DEFAULT_MODE

The default mode which is used to load shared libraries. On OSX 10.3, this is *RTLD_GLOBAL*, otherwise it is the same as *RTLD_LOCAL*.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time:

```
>>> from ctypes import CDLL
>>> libc = CDLL("libc.so.6")  # On Linux
>>> libc.time == libc.time
True
>>> libc['time'] == libc['time']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

PyDLL._handle

The system handle used to access the library.

PyDLL._name

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the **LibraryLoader** class, either by calling the **LoadLibrary()** method, or by retrieving the library as attribute of the loader instance.

class ctypes.LibraryLoader(*dlltype*)

Class which loads shared libraries. *dlltype* should be one of the **CDLL**, **PyDLL**, **WinDLL**, or **OleDLL** types.

__getattr__() has special behavior: It allows loading a shared library by accessing it as attribute of a library loader

instance. The result is cached, so repeated attribute accesses return the same library each time.

LoadLibrary(*name*)

Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available:

ctypes.cdll

Creates **CDLL** instances.

ctypes.windll

Windows only: Creates **WinDLL** instances.

ctypes.oledll

Windows only: Creates **OleDLL** instances.

ctypes.pydll

Creates **PyDLL** instances.

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

ctypes.pythonapi

An instance of **PyDLL** that exposes Python C API functions as attributes. Note that all these functions are assumed to return C int, which is of course not always the truth, so you have to assign the correct **restype** attribute to use these functions.

Loading a library through any of these objects raises an auditing event `ctypes.dlopen` with string argument `name`, the name used to load the library.

Accessing a function on a loaded library raises an auditing event

`ctypes.dlsym` with arguments `library` (the library object) and `name` (the symbol's name as a string or integer).

In cases when only the library handle is available rather than the object, accessing a function raises an auditing event `ctypes.dlsym/handle` with arguments `handle` (the raw library handle) and `name`.

Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class:

class ctypes._FuncPtr

Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

restype

Assign a ctypes type to specify the result type of the foreign function. Use `None` for void, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C int, and the callable will be called with this integer, allowing further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as **`restype`** and assign a callable to the **`errcheck`**

attribute.

argtypes

Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the `stdcall` calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the **`from_param()`** class method of the items in the **`argtypes`** tuple, this method allows adapting the actual argument to an object that the foreign function accepts. For example, a **`c_char_p`** item in the **`argtypes`** tuple will convert a string passed as argument into a bytes object using ctypes conversion rules.

New: It is now possible to put items in argtypes which are not ctypes types, but each item must have a **`from_param()`** method which returns a value usable as argument (integer, string, ctypes instance). This allows defining adapters that can adapt custom objects as function parameters.

errcheck

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

callable(*result*, *func*, *arguments*)

result is what the foreign function returns, as specified by the **`restype`** attribute.

func is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

arguments is a tuple containing the parameters

originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.

exception ctypes.ArgumentError

This exception is raised when a foreign function call cannot convert one of the passed arguments.

On Windows, when a foreign function call raises a system exception (for example, due to an access violation), it will be captured and replaced with a suitable Python exception. Further, an auditing event `ctypes.seh_exception` with argument `code` will be raised, allowing an audit hook to replace the exception with its own.

Some ways to invoke foreign function calls may raise an auditing event `ctypes.call_function` with arguments `function pointer` and `arguments`.

Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function, and can be used as decorator factories, and as such, be applied to functions through the `@wrapper` syntax. See Callback functions for examples.

ctypes.CFUNCTYPE(*restype*, **argtypes*, *use_errno=False*, *use_last_error=False*)

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If *use_errno* is set to true, the ctypes private copy of the system **errno** variable is exchanged with the real **errno** value before and after the call; *use_last_error* does the same for the Windows error code.

ctypes.WINFUNCTYPE(*restype*, **argtypes*, *use_errno=False*, *use_last_error=False*)

Windows only: The returned function prototype creates functions that use the `stdcall` calling convention. The function will release the GIL during the call. *use_errno* and *use_last_error* have the same meaning as above.

ctypes.PYFUNCTYPE(*restype*, **argtypes*)

The returned function prototype creates functions that use the Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call:

prototype(*address*)

Returns a foreign function at the specified address which must be an integer.

prototype(*callable*)

Create a C callable function (a callback function) from a Python *callable*.

prototype(*func_spec*[, *paramflags*])

Returns a foreign function exported by a shared library. *func_spec* must be a 2-tuple `(name_or_ordinal, library)`. The first item is the name of the exported function as string, or the ordinal of the exported function

as small integer. The second item is the shared library instance.

prototype(*vtbl_index*, *name*[, *paramflags*[, *iid*]])

Returns a foreign function that will call a COM method. *vtbl_index* is the index into the virtual function table, a small non-negative integer. *name* is name of the COM method. *iid* is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the **`argtypes`** tuple.

The optional *paramflags* parameter creates foreign function wrappers with much more functionality than the features described above.

paramflags must be a tuple of the same length as **`argtypes`**.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

1

Specifies an input parameter to the function.

2

Output parameter. The foreign function fills in a value.

4

Input parameter which
defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

This example demonstrates how to wrap the Windows `MessageBoxW` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```
WINUSERAPI int WINAPI
MessageBoxW(
    HWND hWnd,
    LPCWSTR lpText,
    LPCWSTR lpCaption,
    UINT uType);
```

Here is the wrapping with **`ctypes`**:

```
>>> from ctypes import c_int, WINFUNCTYPE, windll
>>> from ctypes.wintypes import HWND, LPCWSTR, UINT
>>> prototype = WINFUNCTYPE(c_int, HWND, LPCWSTR, LPCWSTR, UINT)
>>> paramflags = (1, "hwnd", 0), (1, "text", "Hi"), (1,
>>> MessageBox = prototype(("MessageBoxW", windll.user32
```

The `MessageBox` foreign function can now be called in these ways:

```
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
```

A second example demonstrates output parameters. The win32 `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to

supply. Here is the C declaration:

```
WINUSERAPI BOOL WINAPI
GetWindowRect(
     HWND hWnd,
     LPRECT lpRect);
```

Here is the wrapping with **ctypes**:

```
>>> from ctypes import POINTER, WINFUNCTYPE, windll, Wir
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype(("GetWindowRect", windll.u
>>>
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the GetWindowRect function now returns a RECT instance, when called.

Output parameters can be combined with the **errcheck** protocol to do further output processing and error checking. The win32 `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     return args
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

If the **errcheck** function returns the argument tuple it receives unchanged, **ctypes** continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields

in the function and return them instead, the normal processing will no longer take place:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     rc = args[1]
...     return rc.left, rc.top, rc.bottom, rc.right
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

Utility functions

ctypes.addressof(*obj*)

Returns the address of the memory buffer as integer. *obj* must be an instance of a ctypes type.

Raises an auditing event `ctypes.addressof` with argument `obj`.

ctypes.alignment(*obj_or_type*)

Returns the alignment requirements of a ctypes type. *obj_or_type* must be a ctypes type or instance.

ctypes.byref(*obj*[, *offset*])

Returns a light-weight pointer to *obj*, which must be an instance of a ctypes type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

`byref(obj, offset)` corresponds to this C code:

```
(((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

ctypes.cast(*obj*, *type*)

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

ctypes.create_string_buffer(*init_or_size*, *size*=*None*)

This function creates a mutable character buffer. The returned object is a ctypes array of **c_char**.

init_or_size must be an integer which specifies the size of the array, or a bytes object which will be used to initialize the array items.

If a bytes object is specified as first argument, the buffer is made one item larger than its length so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the bytes should not be used.

Raises an auditing event `ctypes.create_string_buffer` with arguments `init, size`.

ctypes.create_unicode_buffer(*init_or_size*, *size*=*None*)

This function creates a mutable unicode character buffer. The returned object is a ctypes array of **c_wchar**.

init_or_size must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

Raises an auditing event

`ctypes.create_unicode_buffer` with arguments `init`, `size`.

ctypes.DllCanUnloadNow()

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllCanUnloadNow function that the _ctypes extension dll exports.

ctypes.DllGetClassObject()

Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllGetClassObject function that the `_ctypes` extension dll exports.

ctypes.util.find_library(*name*)

Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option **`-l`**). If no library can be found, returns `None`.

The exact functionality is system dependent.

ctypes.util.find_msvcrt()

Windows only: return the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

ctypes.FormatError([*code*])

Windows only: Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function GetLastError.

ctypes.GetLastError()

Windows only: Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

ctypes.get_errno()

Returns the current value of the ctypes-private copy of the system **`errno`** variable in the calling thread.

Raises an auditing event `ctypes.get_errno` with no arguments.

ctypes.get_last_error()

Windows only: returns the current value of the ctypes-private copy of the system **`LastError`** variable in the calling thread.

Raises an auditing event `ctypes.get_last_error` with no arguments.

ctypes.memmove(*dst*, *src*, *count*)

Same as the standard C memmove library function: copies *count* bytes from *src* to *dst*. *dst* and *src* must be integers or ctypes instances that can be converted to pointers.

ctypes.memset(*dst*, *c*, *count*)

Same as the standard C memset library function: fills the memory block at address *dst* with *count* bytes of value *c*. *dst* must be an integer specifying an address, or a ctypes instance.

ctypes.POINTER(*type*)

This factory function creates and returns a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. *type* must be a ctypes type.

ctypes.pointer(*obj*)

This function creates a new pointer instance, pointing to *obj*. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

ctypes.resize(*obj*, *size*)

This function resizes the internal memory buffer of *obj*, which must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

ctypes.set_errno(*value*)

Set the current value of the ctypes-private copy of the system **`errno`** variable in the calling thread to *value* and return the previous value.

Raises an auditing event `ctypes.set_errno` with argument `errno`.

ctypes.set_last_error(*value*)

Windows only: set the current value of the ctypes-private copy of the system **`LastError`** variable in the calling thread to *value* and return the previous value.

Raises an auditing event `ctypes.set_last_error` with argument `error`.

ctypes.sizeof(*obj_or_type*)

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C `sizeof` operator.

ctypes.string_at(*address*, *size* = *-1*)

This function returns the C string starting at memory address

address as a bytes object. If size is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

Raises an auditing event `ctypes.string_at` with arguments `address`, `size`.

ctypes.WinError(*code* = *None*, *descr* = *None*)

Windows only: this function is probably the worst-named thing in ctypes. It creates an instance of OSError. If *code* is not specified, `GetLastError` is called to determine the error code. If *descr* is not specified, **`FormatError()`** is called to get a textual description of the error.

Changed in version 3.3: An instance of **`WindowsError`** used to be created.

ctypes.wstring_at(*address*, *size* = *-1*)

This function returns the wide character string starting at memory address *address* as a string. If *size* is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

Raises an auditing event `ctypes.wstring_at` with arguments `address`, `size`.

Data types

class ctypes._CData

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the **`addressof()`** helper function. Another instance variable is exposed as **`_objects`**; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the metaclass):

from_buffer(*source*[, *offset*])

This method returns a ctypes instance that shares the buffer of the *source* object. The *source* object must support the writeable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a **ValueError** is raised.

Raises an auditing event `ctypes.cdata/buffer` with arguments `pointer, size, offset`.

from_buffer_copy(*source*[, *offset*])

This method creates a ctypes instance, copying the buffer from the *source* object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a **ValueError** is raised.

Raises an auditing event `ctypes.cdata/buffer` with arguments `pointer, size, offset`.

from_address(*address*)

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.

This method, and others that indirectly call this method, raises an auditing event `ctypes.cdata` with argument `address`.

from_param(*obj*)

This method adapts *obj* to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's **argtypes** tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns *obj* if that is an instance of the type. Some types accept other objects as well.

in_dll(*library*, *name*)

This method returns a ctypes type instance exported by a shared library. *name* is the name of the symbol that exports the data, *library* is the loaded shared library.

Common instance variables of ctypes data types:

_b_base_

Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The **_b_base_** read-only member is the root ctypes object that owns the memory block.

_b_needsfree_

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

_objects

This member is either `None` or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

Fundamental data types

class ctypes._SimpleCData

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. **_SimpleCData** is a subclass of **_CData**, so it inherits their

methods and attributes. ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

value

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character bytes object or string, for character pointer types it is a Python bytes object or string.

When the `value` attribute is retrieved from a ctypes instance, usually a new object is returned each time. **ctypes** does *not* implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a **restype** of **c_char_p**, you will always receive a Python bytes object, *not* a **c_char_p** instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions **restype** is a subclass of **c_void_p**, you will receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types:

class ctypes.c_byte

Represents the C signed char datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_char

Represents the C char datatype, and interprets the value as a

single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_char_p

Represents the C char* datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a bytes object.

class ctypes.c_double

Represents the C double datatype. The constructor accepts an optional float initializer.

class ctypes.c_longdouble

Represents the C long double datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to **`c_double`**.

class ctypes.c_float

Represents the C float datatype. The constructor accepts an optional float initializer.

class ctypes.c_int

Represents the C signed int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to **`c_long`**.

class ctypes.c_int8

Represents the C 8-bit signed int datatype. Usually an alias for **`c_byte`**.

class ctypes.c_int16

Represents the C 16-bit signed int datatype. Usually an alias for **`c_short`**.

class ctypes.c_int32

Represents the C 32-bit signed int datatype. Usually an alias for **`c_int`**.

class ctypes.c_int64

Represents the C 64-bit signed int datatype. Usually an alias for **`c_longlong`**.

class ctypes.c_long

Represents the C signed long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_longlong

Represents the C signed long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_short

Represents the C signed short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_size_t

Represents the C **`size_t`** datatype.

class ctypes.c_ssize_t

Represents the C **`ssize_t`** datatype.

New in version 3.2.

class ctypes.c_ubyte

Represents the C unsigned char datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_uint

Represents the C unsigned int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for **c_ulong**.

class ctypes.c_uint8

Represents the C 8-bit unsigned int datatype. Usually an alias for **c_ubyte**.

class ctypes.c_uint16

Represents the C 16-bit unsigned int datatype. Usually an alias for **c_ushort**.

class ctypes.c_uint32

Represents the C 32-bit unsigned int datatype. Usually an alias for **c_uint**.

class ctypes.c_uint64

Represents the C 64-bit unsigned int datatype. Usually an alias for **c_ulonglong**.

class ctypes.c_ulong

Represents the C unsigned long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_ulonglong

Represents the C unsigned long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_ushort

Represents the C unsigned short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_void_p

Represents the C void* type. The value is represented as integer. The constructor accepts an optional integer initializer.

class ctypes.c_wchar

Represents the C wchar_t datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_wchar_p

Represents the C wchar_t* datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

class ctypes.c_bool

Represent the C bool datatype (more accurately, _Bool from C99). Its value can be `True` or `False`, and the constructor accepts any object that has a truth value.

class ctypes.HRESULT

Windows only: Represents a **`HRESULT`** value, which contains success or error information for a function or method call.

class ctypes.py_object

Represents the C PyObject* datatype. Calling this without an argument creates a `NULL` PyObject* pointer.

The **`ctypes.wintypes`** module provides quite some other Windows specific data types, for example **`HWND`**, **`WPARAM`**, or **`DWORD`**. Some useful structures like **`MSG`** or **`RECT`** are also defined.

Structured data types

class ctypes.Union(**args*, ***kw*)

Abstract base class for unions in native byte order.

class ctypes.BigEndianUnion(**args*, ***kw*)

Abstract base class for unions in *big endian* byte order.

New in version 3.11.

class ctypes.LittleEndianUnion(**args*, ***kw*)

Abstract base class for unions in *little endian* byte order.

New in version 3.11.

class ctypes.BigEndianStructure(**args*, ***kw*)

Abstract base class for structures in *big endian* byte order.

class ctypes.LittleEndianStructure(**args*, ***kw*)

Abstract base class for structures in *little endian* byte order.

Structures and unions with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

class ctypes.Structure(**args*, ***kw*)

Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a **_fields_** class variable. **ctypes** will create descriptors which allow reading and writing the fields by direct attribute accesses. These are the

fields

A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any ctypes data type.

For integer type fields like **c_int**, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the **_fields_** class variable *after* the class statement that defines the Structure subclass, this allows creating data types that directly or indirectly reference themselves:

```
class List(Structure):
    pass
List._fields_ = [("pnext", POINTER(List)),
                 ...
                ]
```

The **_fields_** class variable must, however, be defined before the type is first used (an instance is created, **sizeof()** is called on it, and so on). Later assignments to the **_fields_** class variable will raise an AttributeError.

It is possible to define sub-subclasses of structure types, they inherit the fields of the base class plus the **_fields_** defined in the sub-subclass, if any.

pack

An optional small integer that allows overriding the alignment of structure fields in the instance. **_pack_** must already be defined when **_fields_** is assigned, otherwise it will have no effect.

anonymous

An optional sequence that lists the names of unnamed (anonymous) fields. **_anonymous_** must be already defined when **_fields_** is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. **ctypes** will create descriptors in the structure type that allows accessing the nested fields

directly, without the need to create the structure or union field.

Here is an example type (Windows):

```
class _U(Union):
    _fields_ = [("lptdesc", POINTER(TYPEDESC)),
                ("lpadesc", POINTER(ARRAYDESC))
                ("hreftype", HREFTYPE)]

class TYPEDESC(Structure):
    _anonymous_ = ("u",)
    _fields_ = [("u", _U),
                ("vt", VARTYPE)]
```

The `TYPEDESC` structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the TYPEDESC instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance:

```
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to define sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate **`_fields_`** variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they are appear in **`_fields_`**. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize **`_fields_`** with the same name, or create new attributes for

names not present in **_fields_**.

Arrays and pointers

class ctypes.Array(**args*)

Abstract base class for arrays.

The recommended way to create concrete array types is by multiplying any **ctypes** data type with a non-negative integer. Alternatively, you can subclass this type and define **_length_** and **_type_** class variables. Array elements can be read and written using standard subscript and slice accesses; for slice reads, the resulting object is *not* itself an **Array**.

length

A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an **IndexError**. Will be returned by **len()**.

type

Specifies the type of each element in the array.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

class ctypes._Pointer

Private, abstract base class for pointers.

Concrete pointer types are created by calling **POINTER()** with the type that will be pointed to; this is done automatically by **pointer()**.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so **len()** will raise **TypeError**. Negative subscripts will read from the memory *before* the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

type

Specifies the type pointed to.

contents

Returns the object to which to pointer points. Assigning to this attribute changes the pointer to point to the assigned object.

Concurrent Execution

The modules described in this chapter provide support for concurrent execution of code. The appropriate choice of tool will depend on the task to be executed (CPU bound vs IO bound) and preferred style of development (event driven cooperative multitasking vs preemptive multitasking). Here's an overview:

- **`threading`** — Thread-based parallelism
  - Thread-Local Data
  - Thread Objects
  - Lock Objects
  - RLock Objects
  - Condition Objects
  - Semaphore Objects
    - **`Semaphore`** Example
  - Event Objects
  - Timer Objects
  - Barrier Objects
  - Using locks, conditions, and semaphores in the **`with`** statement
- **`multiprocessing`** — Process-based parallelism
  - Introduction
    - The **`Process`** class
    - Contexts and start methods
    - Exchanging objects between processes
    - Synchronization between processes
    - Sharing state between processes
    - Using a pool of workers
  - Reference

        - **`Process`** and exceptions
        - Pipes and Queues
        - Miscellaneous
        - Connection Objects
        - Synchronization primitives
        - Shared **`ctypes`** Objects
            - The **`multiprocessing.sharedctypes`** module
        - Managers
            - Customized managers
            - Using a remote manager
        - Proxy Objects
            - Cleanup
        - Process Pools
        - Listeners and Clients
            - Address Formats
        - Authentication keys
        - Logging
        - The **`multiprocessing.dummy`** module
    - Programming guidelines
        - All start methods
        - The *spawn* and *forkserver* start methods
    - Examples

- **`multiprocessing.shared_memory`** — Shared memory for direct access across processes
- The **`concurrent`** package
- **`concurrent.futures`** — Launching parallel tasks
    - Executor Objects
    - ThreadPoolExecutor

        - ThreadPoolExecutor Example
    - ProcessPoolExecutor
        - ProcessPoolExecutor Example
    - Future Objects
    - Module Functions
    - Exception classes
- **`subprocess`** — Subprocess management
    - Using the **`subprocess`** Module
        - Frequently Used Arguments
        - Popen Constructor
        - Exceptions
    - Security Considerations
    - Popen Objects
    - Windows Popen Helpers
        - Windows Constants
    - Older high-level API
    - Replacing Older Functions with the **`subprocess`** Module
        - Replacing **/bin/sh** shell command substitution
        - Replacing shell pipeline
        - Replacing **`os.system()`**
        - Replacing the **`os.spawn`** family
        - Replacing **`os.popen()`**, **`os.popen2()`**, **`os.popen3()`**
        - Replacing functions from the **`popen2`** module
    - Legacy Shell Invocation Functions
    - Notes
        - Converting an argument sequence to a string on Windows
        - Disabling use of **`vfork()`** or **`posix_spawn()`**

- **sched** — Event scheduler
  - Scheduler Objects
- **queue** — A synchronized queue class
  - Queue Objects
  - SimpleQueue Objects
- **contextvars** — Context Variables
  - Context Variables
  - Manual Context Management
  - asyncio support

The following are support modules for some of the above services:

- **_thread** — Low-level threading API

`threading` — Thread-based parallelism

Source code: Lib/threading.py [https://github.com/python/cpython/tree/3.11/Lib/threading.py]

This module constructs higher-level threading interfaces on top of the lower level `_thread` module.

Changed in version 3.7: This module used to be optional, it is now always available.

See also

`concurrent.futures.ThreadPoolExecutor` offers a higher level interface to push tasks to a background thread without blocking execution of the calling thread, while still being able to retrieve their results when needed.

`queue` provides a thread-safe interface for exchanging data between running threads.

`asyncio` offers an alternative approach to achieving task level concurrency without requiring the use of multiple operating system threads.

Note

In the Python 2.x series, this module contained `camelCase` names for some methods and functions. These are deprecated as of Python 3.10, but they are still supported for compatibility with Python 2.5 and lower.

CPython implementation detail: In CPython, due to the Global Interpreter Lock, only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this limitation). If you want your application to make better use of the computational resources of multi-core machines, you are advised to use **multiprocessing** or **concurrent.futures.ProcessPoolExecutor**. However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

This module defines the following functions:

threading.active_count()

Return the number of **Thread** objects currently alive. The returned count is equal to the length of the list returned by **enumerate()**.

The function `activeCount` is a deprecated alias for this function.

threading.current_thread()

Return the current **Thread** object, corresponding to the caller's thread of control. If the caller's thread of control was not created through the **threading** module, a dummy thread object with limited functionality is returned.

The function `currentThread` is a deprecated alias for this function.

threading.excepthook(*args*, */*)

Handle uncaught exception raised by **Thread.run()**.

The *args* argument has the following attributes:

- *exc_type*: Exception type.
- *exc_value*: Exception value, can be `None`.
- *exc_traceback*: Exception traceback, can be `None`.
- *thread*: Thread which raised the exception, can be `None`.

If *exc_type* is **`SystemExit`**, the exception is silently ignored. Otherwise, the exception is printed out on **`sys.stderr`**.

If this function raises an exception, **`sys.excepthook()`** is called to handle it.

`threading.excepthook()` can be overridden to control how uncaught exceptions raised by **`Thread.run()`** are handled.

Storing *exc_value* using a custom hook can create a reference cycle. It should be cleared explicitly to break the reference cycle when the exception is no longer needed.

Storing *thread* using a custom hook can resurrect it if it is set to an object which is being finalized. Avoid storing *thread* after the custom hook completes to avoid resurrecting objects.

See also

`sys.excepthook()` handles uncaught exceptions.

New in version 3.8.

threading._excepthook_

Holds the original value of **`threading.excepthook()`**. It is saved so that the original value can be restored in case they happen to get replaced with broken or alternative objects.

New in version 3.10.

threading.get_ident()

Return the 'thread identifier' of the current thread. This is a nonzero integer. Its value has no direct meaning; it is

intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

New in version 3.3.

threading.get_native_id()

Return the native integral Thread ID of the current thread assigned by the kernel. This is a non-negative integer. Its value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

Availability: Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX.

New in version 3.8.

threading.enumerate()

Return a list of all **Thread** objects currently active. The list includes daemonic threads and dummy thread objects created by **current_thread()**. It excludes terminated threads and threads that have not yet been started. However, the main thread is always part of the result, even when terminated.

threading.main_thread()

Return the main **Thread** object. In normal conditions, the main thread is the thread from which the Python interpreter was started.

New in version 3.4.

threading.settrace(*func*)

Set a trace function for all threads started from the **threading** module. The *func* will be passed to **sys.settrace()** for each thread, before its **run()** method is called.

threading.gettrace()

Get the trace function as set by **settrace()**.

New in version 3.10.

threading.setprofile(*func*)

Set a profile function for all threads started from the **threading** module. The *func* will be passed to **sys.setprofile()** for each thread, before its **run()** method is called.

threading.getprofile()

Get the profiler function as set by **setprofile()**.

New in version 3.10.

threading.stack_size([*size*])

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a **RuntimeError** is raised. If the specified stack size is invalid, a **ValueError** is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information).

Availability: Windows, pthreads.

Unix platforms with POSIX threads support.

This module also defines the following constant:

threading.TIMEOUT_MAX

The maximum value allowed for the *timeout* parameter of blocking functions (**`Lock.acquire()`**, **`RLock.acquire()`**, **`Condition.wait()`**, etc.). Specifying a timeout greater than this value will raise an **`OverflowError`**.

New in version 3.2.

This module defines a number of classes, which are detailed in the sections below.

The design of this module is loosely based on Java's threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python's **`Thread`** class supports a subset of the behavior of Java's Thread class; currently, there are no priorities, no thread groups, and threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java's Thread class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.

Thread-Local Data

Thread-local data is data whose values are thread specific. To manage thread-local data, just create an instance of **`local`** (or a subclass) and store attributes on it:

```
mydata = threading.local()
mydata.x = 1
```

The instance's values will be different for separate threads.

class threading.local

A class that represents thread-local data.

For more details and extensive examples, see the documentation string of the **`_threading_local`** module.

Thread Objects

The `Thread` class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the `run()` method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, *only* override the `__init__()` and `run()` methods of this class.

Once a thread object is created, its activity must be started by calling the thread's `start()` method. This invokes the `run()` method in a separate thread of control.

Once the thread's activity is started, the thread is considered 'alive'. It stops being alive when its `run()` method terminates – either normally, or by raising an unhandled exception. The `is_alive()` method tests whether the thread is alive.

Other threads can call a thread's `join()` method. This blocks the calling thread until the thread whose `join()` method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the `name` attribute.

If the `run()` method raises an exception, `threading.excepthook()` is called to handle it. By default, `threading.excepthook()` ignores silently `SystemExit`.

A thread can be flagged as a "daemon thread". The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the `daemon` property or the *daemon* constructor argument.

Note

Daemon threads are abruptly stopped at shutdown. Their resources (such as open files, database transactions, etc.) may not be released properly. If you want your threads to stop

gracefully, make them non-daemonic and use a suitable signalling mechanism such as an **`Event`**.

There is a “main thread” object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.

There is the possibility that “dummy thread objects” are created. These are thread objects corresponding to “alien threads”, which are threads of control started outside the threading module, such as directly from C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be joined. They are never deleted, since it is impossible to detect the termination of alien threads.

class threading.Thread(*group* = *None*, *target* = *None*, *name* = *None*, *args* = *()*, *kwargs* = *{}*, *, *daemon* = *None*)

This constructor should always be called with keyword arguments. Arguments are:

group should be `None`; reserved for future extension when a **`ThreadGroup`** class is implemented.

target is the callable object to be invoked by the **`run()`** method. Defaults to `None`, meaning nothing is called.

name is the thread name. By default, a unique name is constructed of the form “Thread-*N*” where *N* is a small decimal number, or “Thread-*N* (target)” where “target” is `target.__name__` if the *target* argument is specified.

args is a list or tuple of arguments for the target invocation. Defaults to `()`.

kwargs is a dictionary of keyword arguments for the target invocation. Defaults to `{}`.

If not `None`, *daemon* explicitly sets whether the thread is daemonic. If `None` (the default), the daemonic property is inherited from the current thread.

If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()`) before doing anything else to the thread.

Changed in version 3.10: Use the *target* name if *name* argument is omitted.

Changed in version 3.3: Added the *daemon* argument.

start()

Start the thread's activity.

It must be called at most once per thread object. It arranges for the object's **`run()`** method to be invoked in a separate thread of control.

This method will raise a **`RuntimeError`** if called more than once on the same thread object.

run()

Method representing the thread's activity.

You may override this method in a subclass. The standard **`run()`** method invokes the callable object passed to the object's constructor as the *target* argument, if any, with positional and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

Using list or tuple as the *args* argument which passed to the **`Thread`** could achieve the same effect.

Example:

```
>>> from threading import Thread
>>> t = Thread(target=print, args=[1])
>>> t.run()
1
>>> t = Thread(target=print, args=(1,))
>>> t.run()
```

join(*timeout*=*None*)

Wait until the thread terminates. This blocks the calling thread until the thread whose **`join()`** method is called terminates – either normally or through an unhandled exception – or until the optional timeout occurs.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof). As **`join()`** always returns `None`, you must call **`is_alive()`** after **`join()`** to decide whether a timeout happened – if the thread is still alive, the **`join()`** call timed out.

When the *timeout* argument is not present or `None`, the operation will block until the thread terminates.

A thread can be joined many times.

`join()` raises a **`RuntimeError`** if an attempt is made to join the current thread as that would cause a deadlock. It is also an error to **`join()`** a thread before it has been started and attempts to do so raise the same exception.

name

A string used for identification purposes only. It has no semantics. Multiple threads may be given the same name. The initial name is set by the constructor.

getName()

setName()

Deprecated getter/setter API for **`name`**; use it directly as a property instead.

Deprecated since version 3.10.

ident

The ‘thread identifier’ of this thread or `None` if the thread has not been started. This is a nonzero integer. See the **`get_ident()`** function. Thread identifiers may be recycled when a thread exits and another thread is created. The identifier is available even after the thread has exited.

native_id

The Thread ID (`TID`) of this thread, as assigned by the OS (kernel). This is a non-negative integer, or `None` if the thread has not been started. See the **`get_native_id()`** function. This value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

Note

Similar to Process IDs, Thread IDs are only valid (guaranteed unique system-wide) from the time the thread is created until the thread has been terminated.

Availability: Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX, DragonFlyBSD.

New in version 3.8.

is_alive()

Return whether the thread is alive.

This method returns `True` just before the **`run()`** method starts until just after the **`run()`** method terminates. The module function **`enumerate()`** returns a list of all alive threads.

daemon

A boolean value indicating whether this thread is a daemon thread (`True`) or not (`False`). This must be set before **`start()`** is called, otherwise **`RuntimeError`** is raised. Its initial value is inherited from the creating thread; the main thread is not a daemon thread and therefore all threads created in the main thread default to **`daemon`** = `False`.

The entire Python program exits when no alive non-daemon threads are left.

isDaemon()

setDaemon()

Deprecated getter/setter API for **`daemon`**; use it directly as a property instead.

Deprecated since version 3.10.

Lock Objects

A primitive lock is a synchronization primitive that is not owned by a particular thread when locked. In Python, it is currently the lowest level synchronization primitive available, implemented directly by the **`_thread`** extension module.

A primitive lock is in one of two states, “locked” or “unlocked”. It is created in the unlocked state. It has two basic methods, **`acquire()`** and **`release()`**. When the state is unlocked, **`acquire()`** changes the state to locked and returns immediately. When the state is locked, **`acquire()`** blocks until a call to **`release()`** in another thread changes it to unlocked, then the **`acquire()`** call resets it to locked and returns. The **`release()`** method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a **`RuntimeError`** will be raised.

Locks also support the context management protocol.

When more than one thread is blocked in **`acquire()`** waiting for the state to turn to unlocked, only one thread proceeds when a **`release()`** call resets the state to unlocked; which one of the waiting threads proceeds is not defined, and may vary across implementations.

All methods are executed atomically.

class threading.Lock

The class implementing primitive lock objects. Once a thread has acquired a lock, subsequent attempts to acquire it block, until it is released; any thread may release it.

Note that `Lock` is actually a factory function which returns an instance of the most efficient version of the concrete Lock class that is supported by the platform.

acquire(*blocking* = *True*, *timeout* = *-1*)

Acquire a lock, blocking or non-blocking.

When invoked with the *blocking* argument set to `True` (the default), block until the lock is unlocked, then set it to locked and return `True`.

When invoked with the *blocking* argument set to `False`, do not block. If a call with *blocking* set to `True` would block, return `False` immediately; otherwise, set the lock to locked and return `True`.

When invoked with the floating-point *timeout* argument set to a positive value, block for at most the number of seconds specified by *timeout* and as long as the lock cannot be acquired. A *timeout* argument of `-1` specifies an unbounded wait. It is forbidden to specify a *timeout* when *blocking* is `False`.

The return value is `True` if the lock is acquired successfully, `False` if not (for example if the *timeout* expired).

Changed in version 3.2: The *timeout* parameter is new.

Changed in version 3.2: Lock acquisition can now be interrupted by signals on POSIX if the underlying threading implementation supports it.

release()

Release a lock. This can be called from any thread, not only the thread which has acquired the lock.

When the lock is locked, reset it to unlocked, and return. If any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a **`RuntimeError`** is raised.

There is no return value.

locked()

Return `True` if the lock is acquired.

RLock Objects

A reentrant lock is a synchronization primitive that may be acquired multiple times by the same thread. Internally, it uses the concepts of "owning thread" and "recursion level" in addition to the locked/unlocked state used by primitive locks. In the locked state, some thread owns the lock; in the unlocked state, no thread owns it.

To lock the lock, a thread calls its **`acquire()`** method; this returns once the thread owns the lock. To unlock the lock, a thread calls its **`release()`** method. **`acquire()`**/**`release()`** call pairs may be nested; only the final **`release()`** (the **`release()`** of the outermost pair) resets the lock to unlocked and allows another thread blocked in **`acquire()`** to proceed.

Reentrant locks also support the context management protocol.

class threading.RLock

This class implements reentrant lock objects. A reentrant lock must be released by the thread that acquired it. Once a thread has acquired a reentrant lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

Note that `RLock` is actually a factory function which returns an instance of the most efficient version of the concrete RLock class that is supported by the platform.

acquire(*blocking=True, timeout=-1*)

Acquire a lock, blocking or non-blocking.

When invoked without arguments: if this thread already owns the lock, increment the recursion level by one, and return immediately. Otherwise, if another thread owns the lock, block until the lock is unlocked. Once the lock is unlocked (not owned by any thread), then grab ownership, set the recursion level to one, and return. If more than one thread is blocked waiting until the lock is unlocked, only one at a time will be able to grab ownership of the lock. There is no return value in this case.

When invoked with the *blocking* argument set to `True`, do the same thing as when called without arguments, and return `True`.

When invoked with the *blocking* argument set to `False`, do not block. If a call without an argument would block, return `False` immediately; otherwise, do the same thing as when called without arguments, and return `True`.

When invoked with the floating-point *timeout* argument set to a positive value, block for at most the number of seconds specified by *timeout* and as long as the lock cannot be acquired. Return `True` if the lock has been acquired, `False` if the timeout has elapsed.

Changed in version 3.2: The *timeout* parameter is new.

release()

Release a lock, decrementing the recursion level. If after the decrement it is zero, reset the lock to unlocked (not owned by any thread), and if any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling thread.

Only call this method when the calling thread owns the lock. A **`RuntimeError`** is raised if this method is called when the lock is unlocked.

There is no return value.

Condition Objects

A condition variable is always associated with some kind of lock; this can be passed in or one will be created by default. Passing one in is useful when several condition variables must share the same lock. The lock is part of the condition object: you don't have to track it separately.

A condition variable obeys the context management protocol: using the `with` statement acquires the associated lock for the duration of the enclosed block. The **`acquire()`** and **`release()`** methods also call the corresponding methods of the associated lock.

Other methods must be called with the associated lock held. The **`wait()`** method releases the lock, and then blocks until another thread awakens it by calling **`notify()`** or **`notify_all()`**. Once awakened, **`wait()`** re-acquires the lock and returns. It is also possible to specify a timeout.

The **`notify()`** method wakes up one of the threads waiting for the condition variable, if any are waiting. The **`notify_all()`** method wakes up all threads waiting for the condition variable.

Note: the **`notify()`** and **`notify_all()`** methods don't release the lock; this means that the thread or threads awakened will not

return from their **`wait()`** call immediately, but only when the thread that called **`notify()`** or **`notify_all()`** finally relinquishes ownership of the lock.

The typical programming style using condition variables uses the lock to synchronize access to some shared state; threads that are interested in a particular change of state call **`wait()`** repeatedly until they see the desired state, while threads that modify the state call **`notify()`** or **`notify_all()`** when they change the state in such a way that it could possibly be a desired state for one of the waiters. For example, the following code is a generic producer-consumer situation with unlimited buffer capacity:

```
# Consume one item
with cv:
    while not an_item_is_available():
        cv.wait()
    get_an_available_item()

# Produce one item
with cv:
    make_an_item_available()
    cv.notify()
```

The `while` loop checking for the application's condition is necessary because **`wait()`** can return after an arbitrary long time, and the condition which prompted the **`notify()`** call may no longer hold true. This is inherent to multi-threaded programming. The **`wait_for()`** method can be used to automate the condition checking, and eases the computation of timeouts:

```
# Consume an item
with cv:
    cv.wait_for(an_item_is_available)
    get_an_available_item()
```

To choose between **`notify()`** and **`notify_all()`**, consider whether one state change can be interesting for only one or several waiting threads. E.g. in a typical producer-consumer situation, adding one item to the buffer only needs to wake up one consumer

thread.

class threading.Condition(*lock=None*)

This class implements condition variable objects. A condition variable allows one or more threads to wait until they are notified by another thread.

If the *lock* argument is given and not `None`, it must be a **`Lock`** or **`RLock`** object, and it is used as the underlying lock. Otherwise, a new **`RLock`** object is created and used as the underlying lock.

Changed in version 3.3: changed from a factory function to a class.

acquire(**args*)

Acquire the underlying lock. This method calls the corresponding method on the underlying lock; the return value is whatever that method returns.

release()

Release the underlying lock. This method calls the corresponding method on the underlying lock; there is no return value.

wait(*timeout=None*)

Wait until notified or until a timeout occurs. If the calling thread has not acquired the lock when this method is called, a **`RuntimeError`** is raised.

This method releases the underlying lock, and then blocks until it is awakened by a **`notify()`** or **`notify_all()`** call for the same condition variable in another thread, or until the optional timeout occurs. Once awakened or timed out, it re-acquires the lock and returns.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout

for the operation in seconds (or fractions thereof).

When the underlying lock is an **RLock**, it is not released using its **release()** method, since this may not actually unlock the lock when it was acquired multiple times recursively. Instead, an internal interface of the **RLock** class is used, which really unlocks it even when it has been recursively acquired several times. Another internal interface is then used to restore the recursion level when the lock is reacquired.

The return value is `True` unless a given *timeout* expired, in which case it is `False`.

Changed in version 3.2: Previously, the method always returned `None`.

wait_for(*predicate*, *timeout*=*None*)

Wait until a condition evaluates to true. *predicate* should be a callable which result will be interpreted as a boolean value. A *timeout* may be provided giving the maximum time to wait.

This utility method may call **wait()** repeatedly until the predicate is satisfied, or until a timeout occurs. The return value is the last return value of the predicate and will evaluate to `False` if the method timed out.

Ignoring the timeout feature, calling this method is roughly equivalent to writing:

```
while not predicate():
    cv.wait()
```

Therefore, the same rules apply as with **wait()**: The lock must be held when called and is re-acquired on return. The predicate is evaluated with the lock held.

New in version 3.2.

notify(*n = 1*)

By default, wake up one thread waiting on this condition, if any. If the calling thread has not acquired the lock when this method is called, a **`RuntimeError`** is raised.

This method wakes up at most *n* of the threads waiting for the condition variable; it is a no-op if no threads are waiting.

The current implementation wakes up exactly *n* threads, if at least *n* threads are waiting. However, it's not safe to rely on this behavior. A future, optimized implementation may occasionally wake up more than *n* threads.

Note: an awakened thread does not actually return from its **`wait()`** call until it can reacquire the lock. Since **`notify()`** does not release the lock, its caller should.

notify_all()

Wake up all threads waiting on this condition. This method acts like **`notify()`**, but wakes up all waiting threads instead of one. If the calling thread has not acquired the lock when this method is called, a **`RuntimeError`** is raised.

The method `notifyAll` is a deprecated alias for this method.

Semaphore Objects

This is one of the oldest synchronization primitives in the history of computer science, invented by the early Dutch computer scientist Edsger W. Dijkstra (he used the names `P()` and `V()` instead of **`acquire()`** and **`release()`**).

A semaphore manages an internal counter which is decremented by

each **`acquire()`** call and incremented by each **`release()`** call. The counter can never go below zero; when **`acquire()`** finds that it is zero, it blocks, waiting until some other thread calls **`release()`**.

Semaphores also support the context management protocol.

class threading.Semaphore(*value = 1*)

This class implements semaphore objects. A semaphore manages an atomic counter representing the number of **`release()`** calls minus the number of **`acquire()`** calls, plus an initial value. The **`acquire()`** method blocks if necessary until it can return without making the counter negative. If not given, *value* defaults to 1.

The optional argument gives the initial *value* for the internal counter; it defaults to `1`. If the *value* given is less than 0, **`ValueError`** is raised.

Changed in version 3.3: changed from a factory function to a class.

acquire(*blocking = True*, *timeout = None*)

Acquire a semaphore.

When invoked without arguments:

- If the internal counter is larger than zero on entry, decrement it by one and return `True` immediately.
- If the internal counter is zero on entry, block until awoken by a call to **`release()`**. Once awoken (and the counter is greater than 0), decrement the counter by 1 and return `True`. Exactly one thread will be awoken by each call to **`release()`**. The order in which threads are awoken should not be relied on.

When invoked with *blocking* set to `False`, do not block. If a call without an argument would block, return `False` immediately; otherwise, do the same

thing as when called without arguments, and return `True`.

When invoked with a *timeout* other than `None`, it will block for at most *timeout* seconds. If acquire does not complete successfully in that interval, return `False`. Return `True` otherwise.

Changed in version 3.2: The *timeout* parameter is new.

release(*n=1*)

Release a semaphore, incrementing the internal counter by *n*. When it was zero on entry and other threads are waiting for it to become larger than zero again, wake up *n* of those threads.

Changed in version 3.9: Added the *n* parameter to release multiple waiting threads at once.

class threading.BoundedSemaphore(*value=1*)

Class implementing bounded semaphore objects. A bounded semaphore checks to make sure its current value doesn't exceed its initial value. If it does, **`ValueError`** is raised. In most situations semaphores are used to guard resources with limited capacity. If the semaphore is released too many times it's a sign of a bug. If not given, *value* defaults to 1.

Changed in version 3.3: changed from a factory function to a class.

`Semaphore` Example

Semaphores are often used to guard resources with limited capacity, for example, a database server. In any situation where the size of the resource is fixed, you should use a bounded semaphore. Before spawning any worker threads, your main thread would initialize the semaphore:

```
maxconnections = 5
```

```
# ...
pool_sema = BoundedSemaphore(value=maxconnections)
```

Once spawned, worker threads call the semaphore's acquire and release methods when they need to connect to the server:

```
with pool_sema:
    conn = connectdb()
    try:
        # ... use connection ...
    finally:
        conn.close()
```

The use of a bounded semaphore reduces the chance that a programming error which causes the semaphore to be released more than it's acquired will go undetected.

Event Objects

This is one of the simplest mechanisms for communication between threads: one thread signals an event and other threads wait for it.

An event object manages an internal flag that can be set to true with the **`set()`** method and reset to false with the **`clear()`** method. The **`wait()`** method blocks until the flag is true.

class threading.Event

Class implementing event objects. An event manages a flag that can be set to true with the **`set()`** method and reset to false with the **`clear()`** method. The **`wait()`** method blocks until the flag is true. The flag is initially false.

Changed in version 3.3: changed from a factory function to a class.

is_set()

Return `True` if and only if the internal flag is true.

The method `isSet` is a deprecated alias for this method.

set()

Set the internal flag to true. All threads waiting for it to become true are awakened. Threads that call **`wait()`** once the flag is true will not block at all.

clear()

Reset the internal flag to false. Subsequently, threads calling **`wait()`** will block until **`set()`** is called to set the internal flag to true again.

wait(*timeout*=*None*)

Block until the internal flag is true. If the internal flag is true on entry, return immediately. Otherwise, block until another thread calls **`set()`** to set the flag to true, or until the optional timeout occurs.

When the timeout argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

This method returns `True` if and only if the internal flag has been set to true, either before the wait call or after the wait starts, so it will always return `True` except if a timeout is given and the operation times out.

Changed in version 3.1: Previously, the method always returned `None`.

Timer Objects

This class represents an action that should be run only after a certain amount of time has passed — a timer. **`Timer`** is a subclass of **`Thread`** and as such also functions as an example of creating custom threads.

Timers are started, as with threads, by calling their **`start()`** method. The timer can be stopped (before its action has begun) by

calling the **`cancel()`** method. The interval the timer will wait before executing its action may not be exactly the same as the interval specified by the user.

For example:

```
def hello():
    print("hello, world")

t = Timer(30.0, hello)
t.start()  # after 30 seconds, "hello, world" will be pr
```

class threading.Timer(*interval*, *function*, *args*=*None*, *kwargs*=*None*)

Create a timer that will run *function* with arguments *args* and keyword arguments *kwargs*, after *interval* seconds have passed. If *args* is `None` (the default) then an empty list will be used. If *kwargs* is `None` (the default) then an empty dict will be used.

Changed in version 3.3: changed from a factory function to a class.

cancel()

Stop the timer, and cancel the execution of the timer's action. This will only work if the timer is still in its waiting stage.

Barrier Objects

New in version 3.2.

This class provides a simple synchronization primitive for use by a fixed number of threads that need to wait for each other. Each of the threads tries to pass the barrier by calling the **`wait()`** method and will block until all of the threads have made their **`wait()`** calls. At this point, the threads are released simultaneously.

The barrier can be reused any number of times for the same number of threads.

As an example, here is a simple way to synchronize a client and server thread:

```
b = Barrier(2, timeout=5)

def server():
    start_server()
    b.wait()
    while True:
        connection = accept_connection()
        process_server_connection(connection)

def client():
    b.wait()
    while True:
        connection = make_connection()
        process_client_connection(connection)
```

class threading.Barrier(*parties*, *action*=*None*, *timeout*=*None*)

Create a barrier object for *parties* number of threads. An *action*, when provided, is a callable to be called by one of the threads when they are released. *timeout* is the default timeout value if none is specified for the `wait()` method.

wait(*timeout*=*None*)

Pass the barrier. When all the threads party to the barrier have called this function, they are all released simultaneously. If a *timeout* is provided, it is used in preference to any that was supplied to the class constructor.

The return value is an integer in the range 0 to *parties* – 1, different for each thread. This can be used to select a thread to do some special housekeeping, e.g.:

```
i = barrier.wait()
if i == 0:
    # Only one thread needs to print this
    print("passed the barrier")
```

If an *action* was provided to the constructor, one of the threads will have called it prior to being released. Should this call raise an error, the barrier is put into the broken state.

If the call times out, the barrier is put into the broken state.

This method may raise a **`BrokenBarrierError`** exception if the barrier is broken or reset while a thread is waiting.

reset()

Return the barrier to the default, empty state. Any threads waiting on it will receive the **`BrokenBarrierError`** exception.

Note that using this function may require some external synchronization if there are other threads whose state is unknown. If a barrier is broken it may be better to just leave it and create a new one.

abort()

Put the barrier into a broken state. This causes any active or future calls to **`wait()`** to fail with the **`BrokenBarrierError`**. Use this for example if one of the threads needs to abort, to avoid deadlocking the application.

It may be preferable to simply create the barrier with a sensible *timeout* value to automatically guard against one of the threads going awry.

parties

The number of threads required to pass the barrier.

n_waiting

The number of threads currently waiting in the barrier.

broken

A boolean that is `True` if the barrier is in the broken state.

exception threading.BrokenBarrierError

This exception, a subclass of **`RuntimeError`**, is raised when the **`Barrier`** object is reset or broken.

Using locks, conditions, and semaphores in the **`with`** statement

All of the objects provided by this module that have **`acquire()`** and **`release()`** methods can be used as context managers for a **`with`** statement. The **`acquire()`** method will be called when the block is entered, and **`release()`** will be called when the block is exited. Hence, the following snippet:

```
with some_lock:
    # do something...
```

is equivalent to:

```
some_lock.acquire()
try:
    # do something...
finally:
    some_lock.release()
```

Currently, **`Lock`**, **`RLock`**, **`Condition`**, **`Semaphore`**, and **`BoundedSemaphore`** objects may be used as **`with`** statement context managers.

`multiprocessing` — Process-based parallelism

Source code: Lib/multiprocessing/ [https://github.com/python/cpython/tree/3.11/Lib/multiprocessing/]

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Introduction

`multiprocessing` is a package that supports spawning processes using an API similar to the **`threading`** module. The **`multiprocessing`** package offers both local and remote concurrency, effectively side-stepping the Global Interpreter Lock by using subprocesses instead of threads. Due to this, the **`multiprocessing`** module allows the programmer to fully leverage multiple processors on a given machine. It runs on both Unix and Windows.

The **`multiprocessing`** module also introduces APIs which do not have analogs in the **`threading`** module. A prime example of this is the **`Pool`** object which offers a convenient means of parallelizing the execution of a function across multiple input values, distributing the input data across processes (data parallelism). The following example demonstrates the common practice of defining such functions in a module so that child processes can successfully import that module. This basic example of data parallelism using **`Pool`**,

```
from multiprocessing import Pool

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(5) as p:
        print(p.map(f, [1, 2, 3]))
```

will print to standard output

```
[1, 4, 9]
```

See also

`concurrent.futures.ProcessPoolExecutor` offers a higher level interface to push tasks to a background process without blocking execution of the calling process. Compared to using the **`Pool`** interface directly, the **`concurrent.futures`** API more readily allows the submission of work to the underlying process pool to be separated from waiting for the results.

The **`Process`** class

In **`multiprocessing`**, processes are spawned by creating a **`Process`** object and then calling its **`start()`** method. **`Process`** follows the API of **`threading.Thread`**. A trivial example of a multiprocess program is

```
from multiprocessing import Process

def f(name):
    print('hello', name)

if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

To show the individual process IDs involved, here is an expanded example:

```
from multiprocessing import Process
import os

def info(title):
    print(title)
    print('module name:', __name__)
    print('parent process:', os.getppid())
    print('process id:', os.getpid())

def f(name):
    info('function f')
    print('hello', name)

if __name__ == '__main__':
    info('main line')
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

For an explanation of why the `if __name__ == '__main__'` part is necessary, see Programming guidelines.

Contexts and start methods

Depending on the platform, **`multiprocessing`** supports three ways to start a process. These *start methods* are

spawn

The parent process starts a fresh Python interpreter process. The child process will only inherit those resources necessary to run the process object's **`run()`** method. In particular, unnecessary file descriptors and handles from the parent process will not be inherited. Starting a process using this method is rather slow compared to using *fork*

or *forkserver*.

Available on Unix and Windows. The default on Windows and macOS.

fork

The parent process uses **`os.fork()`** to fork the Python interpreter. The child process, when it begins, is effectively identical to the parent process. All resources of the parent are inherited by the child process. Note that safely forking a multithreaded process is problematic.

Available on Unix only. The default on Unix.

forkserver

When the program starts and selects the *forkserver* start method, a server process is started. From then on, whenever a new process is needed, the parent process connects to the server and requests that it fork a new process. The fork server process is single threaded so it is safe for it to use **`os.fork()`**. No unnecessary resources are inherited.

Available on Unix platforms which support passing file descriptors over Unix pipes.

Changed in version 3.8: On macOS, the *spawn* start method is now the default. The *fork* start method should be considered unsafe as it can lead to crashes of the subprocess. See bpo-33725 [https://bugs.python.org/issue?@action=redirect&bpo=33725].

Changed in version 3.4: spawn added on all Unix platforms, and *forkserver* added for some Unix platforms. Child processes no longer inherit all of the parents inheritable handles on Windows.

On Unix using the *spawn* or *forkserver* start methods will also start a *resource tracker* process which tracks the unlinked named system

resources (such as named semaphores or **SharedMemory** objects) created by processes of the program. When all processes have exited the resource tracker unlinks any remaining tracked object. Usually there should be none, but if a process was killed by a signal there may be some “leaked” resources. (Neither leaked semaphores nor shared memory segments will be automatically unlinked until the next reboot. This is problematic for both objects because the system allows only a limited number of named semaphores, and shared memory segments occupy some space in the main memory.)

To select a start method you use the **set_start_method()** in the `if __name__ == '__main__'` clause of the main module. For example:

```
import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    mp.set_start_method('spawn')
    q = mp.Queue()
    p = mp.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()
```

set_start_method() should not be used more than once in the program.

Alternatively, you can use **get_context()** to obtain a context object. Context objects have the same API as the multiprocessing module, and allow one to use multiple start methods in the same program.

```
import multiprocessing as mp

def foo(q):
    q.put('hello')
```

```
if __name__ == '__main__':
    ctx = mp.get_context('spawn')
    q = ctx.Queue()
    p = ctx.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()
```

Note that objects related to one context may not be compatible with processes for a different context. In particular, locks created using the *fork* context cannot be passed to processes started using the *spawn* or *forkserver* start methods.

A library which wants to use a particular start method should probably use `get_context()` to avoid interfering with the choice of the library user.

Warning

The `'spawn'` and `'forkserver'` start methods cannot currently be used with “frozen” executables (i.e., binaries produced by packages like **PyInstaller** and **cx_Freeze**) on Unix. The `'fork'` start method does work.

Exchanging objects between processes

`multiprocessing` supports two types of communication channel between processes:

Queues

The `Queue` class is a near clone of `queue.Queue`. For example:

```
from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])
```

```
if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print(q.get())    # prints "[42, None, 'hello'
    p.join()
```

Queues are thread and process safe.

Pipes

The **`Pipe()`** function returns a pair of connection objects connected by a pipe which by default is duplex (two-way). For example:

```
from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()

if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print(parent_conn.recv())   # prints "[42, Nor
    p.join()
```

The two connection objects returned by **`Pipe()`** represent the two ends of the pipe. Each connection object has **`send()`** and **`recv()`** methods (among others). Note that data in a pipe may become corrupted if two processes (or threads) try to read from or write to the *same* end of the pipe at the same time. Of course there is no risk of corruption from processes using different ends of the pipe at the same time.

Synchronization between processes

multiprocessing contains equivalents of all the synchronization primitives from **threading**. For instance one can use a lock to ensure that only one process prints to standard output at a time:

```
from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    try:
        print('hello world', i)
    finally:
        l.release()

if __name__ == '__main__':
    lock = Lock()

    for num in range(10):
        Process(target=f, args=(lock, num)).start()
```

Without using the lock output from the different processes is liable to get all mixed up.

Sharing state between processes

As mentioned above, when doing concurrent programming it is usually best to avoid using shared state as far as possible. This is particularly true when using multiple processes.

However, if you really do need to use some shared data then **multiprocessing** provides a couple of ways of doing so.

Shared memory

Data can be stored in a shared memory map using **Value** or **Array**. For example, the following code

```
from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
```

```
        for i in range(len(a)):
            a[i] = -a[i]

    if __name__ == '__main__':
        num = Value('d', 0.0)
        arr = Array('i', range(10))

        p = Process(target=f, args=(num, arr))
        p.start()
        p.join()

        print(num.value)
        print(arr[:])
```

will print

```
3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
```

The `'d'` and `'i'` arguments used when creating `num` and `arr` are typecodes of the kind used by the **`array`** module: `'d'` indicates a double precision float and `'i'` indicates a signed integer. These shared objects will be process and thread-safe.

For more flexibility in using shared memory one can use the **`multiprocessing.sharedctypes`** module which supports the creation of arbitrary ctypes objects allocated from shared memory.

Server process

A manager object returned by **`Manager()`** controls a server process which holds Python objects and allows other processes to manipulate them using proxies.

A manager returned by **`Manager()`** will support types **`list`**, **`dict`**, **`Namespace`**, **`Lock`**, **`RLock`**, **`Semaphore`**, **`BoundedSemaphore`**, **`Condition`**,

Event, **Barrier**, **Queue**, **Value** and **Array**. For example,

```
from multiprocessing import Process, Manager

def f(d, l):
    d[1] = '1'
    d['2'] = 2
    d[0.25] = None
    l.reverse()

if __name__ == '__main__':
    with Manager() as manager:
        d = manager.dict()
        l = manager.list(range(10))

        p = Process(target=f, args=(d, l))
        p.start()
        p.join()

        print(d)
        print(l)
```

will print

```
{0.25: None, 1: '1', '2': 2}
[9, 8, 7, 6, 5, 4, 3, 2, 1, 0]
```

Server process managers are more flexible than using shared memory objects because they can be made to support arbitrary object types. Also, a single manager can be shared by processes on different computers over a network. They are, however, slower than using shared memory.

Using a pool of workers

The **Pool** class represents a pool of worker processes. It has methods which allows tasks to be offloaded to the worker processes in a few different ways.

For example:

```
from multiprocessing import Pool, TimeoutError
import time
import os

def f(x):
    return x*x

if __name__ == '__main__':
    # start 4 worker processes
    with Pool(processes=4) as pool:

        # print "[0, 1, 4,..., 81]"
        print(pool.map(f, range(10)))

        # print same numbers in arbitrary order
        for i in pool.imap_unordered(f, range(10)):
            print(i)

        # evaluate "f(20)" asynchronously
        res = pool.apply_async(f, (20,))      # runs in
        print(res.get(timeout=1))             # prints "

        # evaluate "os.getpid()" asynchronously
        res = pool.apply_async(os.getpid, ()) # runs in
        print(res.get(timeout=1))             # prints t

        # launching multiple evaluations asynchronously
        multiple_results = [pool.apply_async(os.getpid,
        print([res.get(timeout=1) for res in multiple_re

        # make a single worker sleep for 10 seconds
        res = pool.apply_async(time.sleep, (10,))
        try:
            print(res.get(timeout=1))
        except TimeoutError:
            print("We lacked patience and got a multipro
```

```
        print("For the moment, the pool remains availabl

    # exiting the 'with'-block has stopped the pool
    print("Now the pool is closed and no longer availabl
```

Note that the methods of a pool should only ever be used by the process which created it.

Note

Functionality within this package requires that the `__main__` module be importable by the children. This is covered in Programming guidelines however it is worth pointing out here. This means that some examples, such as the **`multiprocessing.pool.Pool`** examples will not work in the interactive interpreter. For example:

```
>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> def f(x):
...     return x*x
...
>>> with p:
...   p.map(f, [1,2,3])
Process PoolWorker-1:
Process PoolWorker-2:
Process PoolWorker-3:
Traceback (most recent call last):
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'
```

(If you try this it will actually output three full tracebacks interleaved in a semi-random fashion, and then you may have to stop the parent process somehow.)

Reference

The **multiprocessing** package mostly replicates the API of the **threading** module.

Process and exceptions

class multiprocessing.Process(*group* = *None*, *target* = *None*, *name* = *None*, *args* = *()*, *kwargs* = *{}*, ***, *daemon* = *None*)

Process objects represent activity that is run in a separate process. The **Process** class has equivalents of all the methods of **threading.Thread**.

The constructor should always be called with keyword arguments. *group* should always be `None`; it exists solely for compatibility with **threading.Thread**. *target* is the callable object to be invoked by the **run()** method. It defaults to `None`, meaning nothing is called. *name* is the process name (see **name** for more details). *args* is the argument tuple for the target invocation. *kwargs* is a dictionary of keyword arguments for the target invocation. If provided, the keyword-only *daemon* argument sets the process **daemon** flag to `True` or `False`. If `None` (the default), this flag will be inherited from the creating process.

By default, no arguments are passed to *target*. The *args* argument, which defaults to `()`, can be used to specify a list or tuple of the arguments to pass to *target*.

If a subclass overrides the constructor, it must make sure it invokes the base class constructor (**Process.__init__()**) before doing anything else to the process.

Changed in version 3.3: Added the *daemon* argument.

run()

Method representing the process's activity.

You may override this method in a subclass. The standard **run()** method invokes the callable object passed to the object's constructor as the target argument, if any, with sequential and keyword

arguments taken from the *args* and *kwargs* arguments, respectively.

Using a list or tuple as the *args* argument passed to **`Process`** achieves the same effect.

Example:

```
>>> from multiprocessing import Process
>>> p = Process(target=print, args=[1])
>>> p.run()
1
>>> p = Process(target=print, args=(1,))
>>> p.run()
1
```

start()

Start the process's activity.

This must be called at most once per process object. It arranges for the object's **`run()`** method to be invoked in a separate process.

join([*timeout*])

If the optional argument *timeout* is `None` (the default), the method blocks until the process whose **`join()`** method is called terminates. If *timeout* is a positive number, it blocks at most *timeout* seconds. Note that the method returns `None` if its process terminates or if the method times out. Check the process's **`exitcode`** to determine if it terminated.

A process can be joined many times.

A process cannot join itself because this would cause a deadlock. It is an error to attempt to join a process before it has been started.

name

The process's name. The name is a string used for identification purposes only. It has no semantics. Multiple processes may be given the same name.

The initial name is set by the constructor. If no explicit name is provided to the constructor, a name of the form 'Process-N_1:N_2:…:N_k' is constructed, where each N_k is the N-th child of its parent.

is_alive()

Return whether the process is alive.

Roughly, a process object is alive from the moment the **`start()`** method returns until the child process terminates.

daemon

The process's daemon flag, a Boolean value. This must be set before **`start()`** is called.

The initial value is inherited from the creating process.

When a process exits, it attempts to terminate all of its daemonic child processes.

Note that a daemonic process is not allowed to create child processes. Otherwise a daemonic process would leave its children orphaned if it gets terminated when its parent process exits. Additionally, these are **not** Unix daemons or services, they are normal processes that will be terminated (and not joined) if non-daemonic processes have exited.

In addition to the **`threading.Thread`** API, **`Process`** objects also support the following attributes and methods:

pid

Return the process ID. Before the process is spawned, this will be `None`.

exitcode

The child's exit code. This will be `None` if the process has not yet terminated.

If the child's **`run()`** method returned normally, the exit code will be 0. If it terminated via **`sys.exit()`** with an integer argument *N*, the exit code will be *N*.

If the child terminated due to an exception not caught within **`run()`**, the exit code will be 1. If it was terminated by signal *N*, the exit code will be the negative value *-N*.

authkey

The process's authentication key (a byte string).

When **`multiprocessing`** is initialized the main process is assigned a random string using **`os.urandom()`**.

When a **`Process`** object is created, it will inherit the authentication key of its parent process, although this may be changed by setting **`authkey`** to another byte string.

See Authentication keys.

sentinel

A numeric handle of a system object which will become "ready" when the process ends.

You can use this value if you want to wait on several events at once using **`multiprocessing.connection.wait()`**. Otherwise calling **`join()`** is simpler.

On Windows, this is an OS handle usable with the `WaitForSingleObject` and `WaitForMultipleObjects` family of API calls. On Unix, this is a file descriptor usable with primitives

from the **select** module.

New in version 3.3.

terminate()

Terminate the process. On Unix this is done using the SIGTERM signal; on Windows **TerminateProcess()** is used. Note that exit handlers and finally clauses, etc., will not be executed.

Note that descendant processes of the process will *not* be terminated – they will simply become orphaned.

Warning

If this method is used when the associated process is using a pipe or queue then the pipe or queue is liable to become corrupted and may become unusable by other process. Similarly, if the process has acquired a lock or semaphore etc. then terminating it is liable to cause other processes to deadlock.

kill()

Same as **terminate()** but using the SIGKILL signal on Unix.

New in version 3.7.

close()

Close the **Process** object, releasing all resources associated with it. **ValueError** is raised if the underlying process is still running. Once **close()** returns successfully, most other methods and attributes of the **Process** object will raise **ValueError**.

New in version 3.7.

Note that the **start()**, **join()**, **is_alive()**, **terminate()** and **exitcode** methods should only be called by the process that created the process object.

Example usage of some of the methods of **Process**:

```
>>> import multiprocessing, time, signal
>>> p = multiprocessing.Process(target=time.sleep,
>>> print(p, p.is_alive())
<Process ... initial> False
>>> p.start()
>>> print(p, p.is_alive())
<Process ... started> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print(p, p.is_alive())
<Process ... stopped exitcode=-SIGTERM> False
>>> p.exitcode == -signal.SIGTERM
True
```

exception multiprocessing.ProcessError

The base class of all **multiprocessing** exceptions.

exception multiprocessing.BufferTooShort

Exception raised by **Connection.recv_bytes_into()** when the supplied buffer object is too small for the message read.

If `e` is an instance of **BufferTooShort** then `e.args[0]` will give the message as a byte string.

exception multiprocessing.AuthenticationError

Raised when there is an authentication error.

exception multiprocessing.TimeoutError

Raised by methods with a timeout when the timeout expires.

Pipes and Queues

When using multiple processes, one generally uses message passing for communication between processes and avoids having to use any synchronization primitives like locks.

For passing messages one can use `Pipe()` (for a connection between two processes) or a queue (which allows multiple producers and consumers).

The `Queue`, `SimpleQueue` and `JoinableQueue` types are multi-producer, multi-consumer FIFO queues modelled on the `queue.Queue` class in the standard library. They differ in that `Queue` lacks the `task_done()` and `join()` methods introduced into Python 2.5's `queue.Queue` class.

If you use `JoinableQueue` then you **must** call `JoinableQueue.task_done()` for each task removed from the queue or else the semaphore used to count the number of unfinished tasks may eventually overflow, raising an exception.

Note that one can also create a shared queue by using a manager object – see Managers.

Note

`multiprocessing` uses the usual `queue.Empty` and `queue.Full` exceptions to signal a timeout. They are not available in the `multiprocessing` namespace so you need to import them from `queue`.

Note

When an object is put on a queue, the object is pickled and a background thread later flushes the pickled data to an underlying pipe. This has some consequences which are a little surprising, but should not cause any practical difficulties – if they really bother you then you can instead use a queue created with a manager.

1. After putting an object on an empty queue there may be an infinitesimal delay before the queue's `empty()` method

returns **`False`** and **`get_nowait()`** can return without raising **`queue.Empty`**.

2. If multiple processes are enqueuing objects, it is possible for the objects to be received at the other end out-of-order. However, objects enqueued by the same process will always be in the expected order with respect to each other.

Warning

If a process is killed using **`Process.terminate()`** or **`os.kill()`** while it is trying to use a **`Queue`**, then the data in the queue is likely to become corrupted. This may cause any other process to get an exception when it tries to use the queue later on.

Warning

As mentioned above, if a child process has put items on a queue (and it has not used **`JoinableQueue.cancel_join_thread`**), then that process will not terminate until all buffered items have been flushed to the pipe.

This means that if you try joining that process you may get a deadlock unless you are sure that all items which have been put on the queue have been consumed. Similarly, if the child process is non-daemonic then the parent process may hang on exit when it tries to join all its non-daemonic children.

Note that a queue created using a manager does not have this issue. See Programming guidelines.

For an example of the usage of queues for interprocess communication see Examples.

multiprocessing.Pipe([*duplex*])

Returns a pair `(conn1, conn2)` of **`Connection`** objects representing the ends of a pipe.

If *duplex* is `True` (the default) then the pipe is bidirectional. If *duplex* is `False` then the pipe is unidirectional: `conn1` can only be used for receiving messages and `conn2` can only be used for sending messages.

class multiprocessing.Queue([*maxsize*])

Returns a process shared queue implemented using a pipe and a few locks/semaphores. When a process first puts an item on the queue a feeder thread is started which transfers objects from a buffer into the pipe.

The usual **`queue.Empty`** and **`queue.Full`** exceptions from the standard library's **`queue`** module are raised to signal timeouts.

`Queue` implements all the methods of **`queue.Queue`** except for **`task_done()`** and **`join()`**.

qsize()

Return the approximate size of the queue. Because of multithreading/multiprocessing semantics, this number is not reliable.

Note that this may raise **`NotImplementedError`** on Unix platforms like macOS where `sem_getvalue()` is not implemented.

empty()

Return `True` if the queue is empty, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

full()

Return `True` if the queue is full, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

put(*obj*[, *block*[, *timeout*]])

Put obj into the queue. If the optional argument *block* is `True` (the default) and *timeout* is `None` (the default), block if necessary until a free slot is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the **`queue.Full`** exception if no free slot was available within that time. Otherwise (*block* is `False`), put an item on the queue if a free slot is immediately available, else raise the **`queue.Full`** exception (*timeout* is ignored in that case).

Changed in version 3.8: If the queue is closed, **`ValueError`** is raised instead of **`AssertionError`**.

put_nowait(*obj*)

Equivalent to `put(obj, False)`.

get([*block*[, *timeout*]])

Remove and return an item from the queue. If optional args *block* is `True` (the default) and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the **`queue.Empty`** exception if no item was available within that time. Otherwise (block is `False`), return an item if one is immediately available, else raise the **`queue.Empty`** exception (*timeout* is ignored in that case).

Changed in version 3.8: If the queue is closed, **`ValueError`** is raised instead of **`OSError`**.

get_nowait()

Equivalent to `get(False)`.

`multiprocessing.Queue` has a few additional methods not found in **`queue.Queue`**. These methods are usually unnecessary for most code:

close()

Indicate that no more data will be put on this queue by the current process. The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.

join_thread()

Join the background thread. This can only be used after **close()** has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue's background thread. The process can call **cancel_join_thread()** to make **join_thread()** do nothing.

cancel_join_thread()

Prevent **join_thread()** from blocking. In particular, this prevents the background thread from being joined automatically when the process exits – see **join_thread()**.

A better name for this method might be `allow_exit_without_flush()`. It is likely to cause enqueued data to be lost, and you almost certainly will not need to use it. It is really only there if you need the current process to exit immediately without waiting to flush enqueued data to the underlying pipe, and you don't care about lost data.

Note

This class's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the functionality in this class will be disabled, and attempts to instantiate a **Queue** will result in an **ImportError**. See bpo-3770 [https://bugs.python.org/

issue?@action=redirect&bpo=3770] for additional information. The same holds true for any of the specialized queue types listed below.

class multiprocessing.SimpleQueue

It is a simplified **Queue** type, very close to a locked **Pipe**.

close()

Close the queue: release internal resources.

A queue must not be used anymore after it is closed. For example, **get()**, **put()** and **empty()** methods must no longer be called.

New in version 3.9.

empty()

Return `True` if the queue is empty, `False` otherwise.

get()

Remove and return an item from the queue.

put(*item*)

Put *item* into the queue.

class multiprocessing.JoinableQueue([*maxsize*])

JoinableQueue, a **Queue** subclass, is a queue which additionally has **task_done()** and **join()** methods.

task_done()

Indicate that a formerly enqueued task is complete. Used by queue consumers. For each **get()** used to fetch a task, a subsequent call to **task_done()** tells the queue that the processing on the task is complete.

If a **join()** is currently blocking, it will resume when

all items have been processed (meaning that a **`task_done()`** call was received for every item that had been **`put()`** into the queue).

Raises a **`ValueError`** if called more times than there were items placed in the queue.

join()

Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer calls **`task_done()`** to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, **`join()`** unblocks.

Miscellaneous

multiprocessing.active_children()

Return list of all live children of the current process.

Calling this has the side effect of “joining” any processes which have already finished.

multiprocessing.cpu_count()

Return the number of CPUs in the system.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with `len(os.sched_getaffinity(0))`

When the number of CPUs cannot be determined a **`NotImplementedError`** is raised.

See also

`os.cpu_count()`

multiprocessing.current_process()

Return the **Process** object corresponding to the current process.

An analogue of **threading.current_thread()**.

multiprocessing.parent_process()

Return the **Process** object corresponding to the parent process of the **current_process()**. For the main process, `parent_process` will be `None`.

New in version 3.8.

multiprocessing.freeze_support()

Add support for when a program which uses **multiprocessing** has been frozen to produce a Windows executable. (Has been tested with **py2exe**, **PyInstaller** and **cx_Freeze**.)

One needs to call this function straight after the `if __name__ == '__main__'` line of the main module. For example:

```
from multiprocessing import Process, freeze_support

def f():
    print('hello world!')

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

If the `freeze_support()` line is omitted then trying to run the frozen executable will raise **RuntimeError**.

Calling `freeze_support()` has no effect when invoked on any operating system other than Windows. In addition, if the module is being run normally by the Python interpreter on

Windows (the program has not been frozen), then `freeze_support()` has no effect.

multiprocessing.get_all_start_methods()

Returns a list of the supported start methods, the first of which is the default. The possible start methods are `'fork'`, `'spawn'` and `'forkserver'`. On Windows only `'spawn'` is available. On Unix `'fork'` and `'spawn'` are always supported, with `'fork'` being the default.

New in version 3.4.

multiprocessing.get_context(*method=None*)

Return a context object which has the same attributes as the **multiprocessing** module.

If *method* is `None` then the default context is returned. Otherwise *method* should be `'fork'`, `'spawn'`, `'forkserver'`. **ValueError** is raised if the specified start method is not available.

New in version 3.4.

multiprocessing.get_start_method(*allow_none=False*)

Return the name of start method used for starting processes.

If the start method has not been fixed and *allow_none* is false, then the start method is fixed to the default and the name is returned. If the start method has not been fixed and *allow_none* is true then `None` is returned.

The return value can be `'fork'`, `'spawn'`, `'forkserver'` or `None`. `'fork'` is the default on Unix, while `'spawn'` is the default on Windows and macOS.

Changed in version 3.8: On macOS, the *spawn* start method is now the default. The *fork* start method should be considered unsafe as it can lead to crashes of the subprocess. See bpo-33725 [https://bugs.python.org/issue?@action=redirect&bpo=33725].

New in version 3.4.

multiprocessing.set_executable(*executable*)

Set the path of the Python interpreter to use when starting a child process. (By default **sys.executable** is used). Embedders will probably need to do some thing like

```
set_executable(os.path.join(sys.exec_prefix, 'pytho
```

before they can create child processes.

Changed in version 3.4: Now supported on Unix when the `'spawn'` start method is used.

Changed in version 3.11: Accepts a path-like object.

multiprocessing.set_start_method(*method*, *force=False*)

Set the method which should be used to start child processes. The *method* argument can be `'fork'`, `'spawn'` or `'forkserver'`. Raises **RuntimeError** if the start method has already been set and *force* is not `True`. If *method* is `None` and *force* is `True` then the start method is set to `None`. If *method* is `None` and *force* is `False` then the context is set to the default context.

Note that this should be called at most once, and it should be protected inside the `if __name__ == '__main__'` clause of the main module.

New in version 3.4.

Note

multiprocessing contains no analogues of **threading.active_count()**, **threading.enumerate()**, **threading.settrace()**, **threading.setprofile()**, **threading.Timer**, or **threading.local**.

Connection Objects

Connection objects allow the sending and receiving of picklable objects or strings. They can be thought of as message oriented connected sockets.

Connection objects are usually created using **`Pipe`** – see also Listeners and Clients.

class multiprocessing.connection.Connection

send(*obj*)

Send an object to the other end of the connection which should be read using **`recv()`**.

The object must be picklable. Very large pickles (approximately 32 MiB+, though it depends on the OS) may raise a **`ValueError`** exception.

recv()

Return an object sent from the other end of the connection using **`send()`**. Blocks until there is something to receive. Raises **`EOFError`** if there is nothing left to receive and the other end was closed.

fileno()

Return the file descriptor or handle used by the connection.

close()

Close the connection.

This is called automatically when the connection is garbage collected.

poll([*timeout*])

Return whether there is any data available to be read.

If *timeout* is not specified then it will return immediately. If *timeout* is a number then this specifies

the maximum time in seconds to block. If *timeout* is `None` then an infinite timeout is used.

Note that multiple connection objects may be polled at once by using **`multiprocessing.connection.wait()`**.

send_bytes(*buffer*[, *offset*[, *size*]])

Send byte data from a bytes-like object as a complete message.

If *offset* is given then data is read from that position in *buffer*. If *size* is given then that many bytes will be read from buffer. Very large buffers (approximately 32 MiB +, though it depends on the OS) may raise a **`ValueError`** exception

recv_bytes([*maxlength*])

Return a complete message of byte data sent from the other end of the connection as a string. Blocks until there is something to receive. Raises **`EOFError`** if there is nothing left to receive and the other end has closed.

If *maxlength* is specified and the message is longer than *maxlength* then **`OSError`** is raised and the connection will no longer be readable.

Changed in version 3.3: This function used to raise **`IOError`**, which is now an alias of **`OSError`**.

recv_bytes_into(*buffer*[, *offset*])

Read into *buffer* a complete message of byte data sent from the other end of the connection and return the number of bytes in the message. Blocks until there is something to receive. Raises **`EOFError`** if there is nothing left to receive and the other end was closed.

buffer must be a writable bytes-like object. If *offset* is

given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of *buffer* (in bytes).

If the buffer is too short then a **BufferTooShort** exception is raised and the complete message is available as `e.args[0]` where `e` is the exception instance.

Changed in version 3.3: Connection objects themselves can now be transferred between processes using **Connection.send()** and **Connection.recv()**.

New in version 3.3: Connection objects now support the context management protocol – see Context Manager Types. **__enter__()** returns the connection object, and **__exit__()** calls **close()**.

For example:

```
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes(b'thank you')
>>> a.recv_bytes()
b'thank you'
>>> import array
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> a.send_bytes(arr1)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])
```

Warning

The **`Connection.recv()`** method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message.

Therefore, unless the connection object was produced using **`Pipe()`** you should only use the **`recv()`** and **`send()`** methods after performing some sort of authentication. See Authentication keys.

Warning

If a process is killed while it is trying to read or write to a pipe then the data in the pipe is likely to become corrupted, because it may become impossible to be sure where the message boundaries lie.

Synchronization primitives

Generally synchronization primitives are not as necessary in a multiprocess program as they are in a multithreaded program. See the documentation for **`threading`** module.

Note that one can also create synchronization primitives by using a manager object – see Managers.

class multiprocessing.Barrier(*parties*[, *action*[, *timeout*]])

A barrier object: a clone of **`threading.Barrier`**.

New in version 3.3.

class multiprocessing.BoundedSemaphore([*value*])

A bounded semaphore object: a close analog of **`threading.BoundedSemaphore`**.

A solitary difference from its close analog exists: its `acquire` method's first argument is named *block*, as is consistent with **`Lock.acquire()`**.

Note

On macOS, this is indistinguishable from **Semaphore** because `sem_getvalue()` is not implemented on that platform.

class multiprocessing.Condition([*lock*])

A condition variable: an alias for **threading.Condition**.

If *lock* is specified then it should be a **Lock** or **RLock** object from **multiprocessing**.

Changed in version 3.3: The **wait_for()** method was added.

class multiprocessing.Event

A clone of **threading.Event**.

class multiprocessing.Lock

A non-recursive lock object: a close analog of **threading.Lock**. Once a process or thread has acquired a lock, subsequent attempts to acquire it from any process or thread will block until it is released; any process or thread may release it. The concepts and behaviors of **threading.Lock** as it applies to threads are replicated here in **multiprocessing.Lock** as it applies to either processes or threads, except as noted.

Note that **Lock** is actually a factory function which returns an instance of `multiprocessing.synchronize.Lock` initialized with a default context.

Lock supports the context manager protocol and thus may be used in **with** statements.

acquire(*block* = *True*, *timeout* = *None*)

Acquire a lock, blocking or non-blocking.

With the *block* argument set to `True` (the default), the

method call will block until the lock is in an unlocked state, then set it to locked and return `True`. Note that the name of this first argument differs from that in **`threading.Lock.acquire()`**.

With the *block* argument set to `False`, the method call does not block. If the lock is currently in a locked state, return `False`; otherwise set the lock to a locked state and return `True`.

When invoked with a positive, floating-point value for *timeout*, block for at most the number of seconds specified by *timeout* as long as the lock can not be acquired. Invocations with a negative value for *timeout* are equivalent to a *timeout* of zero. Invocations with a *timeout* value of `None` (the default) set the timeout period to infinite. Note that the treatment of negative or `None` values for *timeout* differs from the implemented behavior in **`threading.Lock.acquire()`**. The *timeout* argument has no practical implications if the *block* argument is set to `False` and is thus ignored. Returns `True` if the lock has been acquired or `False` if the timeout period has elapsed.

release()

Release a lock. This can be called from any process or thread, not only the process or thread which originally acquired the lock.

Behavior is the same as in **`threading.Lock.release()`** except that when invoked on an unlocked lock, a **`ValueError`** is raised.

class multiprocessing.RLock

A recursive lock object: a close analog of **`threading.RLock`**. A recursive lock must be released by the process or thread that acquired it. Once a process or thread has acquired a recursive lock, the same process or thread may acquire it again without blocking; that process or thread must

release it once for each time it has been acquired.

Note that **`RLock`** is actually a factory function which returns an instance of `multiprocessing.synchronize.RLock` initialized with a default context.

`RLock` supports the context manager protocol and thus may be used in **`with`** statements.

acquire(*block*=*True*, *timeout*=*None*)

Acquire a lock, blocking or non-blocking.

When invoked with the *block* argument set to `True`, block until the lock is in an unlocked state (not owned by any process or thread) unless the lock is already owned by the current process or thread. The current process or thread then takes ownership of the lock (if it does not already have ownership) and the recursion level inside the lock increments by one, resulting in a return value of `True`. Note that there are several differences in this first argument's behavior compared to the implementation of **`threading.RLock.acquire()`**, starting with the name of the argument itself.

When invoked with the *block* argument set to `False`, do not block. If the lock has already been acquired (and thus is owned) by another process or thread, the current process or thread does not take ownership and the recursion level within the lock is not changed, resulting in a return value of `False`. If the lock is in an unlocked state, the current process or thread takes ownership and the recursion level is incremented, resulting in a return value of `True`.

Use and behaviors of the *timeout* argument are the same as in **`Lock.acquire()`**. Note that some of these behaviors of *timeout* differ from the implemented behaviors in **`threading.RLock.acquire()`**.

release()

Release a lock, decrementing the recursion level. If after the decrement the recursion level is zero, reset the lock to unlocked (not owned by any process or thread) and if any other processes or threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling process or thread.

Only call this method when the calling process or thread owns the lock. An **`AssertionError`** is raised if this method is called by a process or thread other than the owner or if the lock is in an unlocked (unowned) state. Note that the type of exception raised in this situation differs from the implemented behavior in **`threading.RLock.release()`**.

class multiprocessing.Semaphore([*value*])

A semaphore object: a close analog of **`threading.Semaphore`**.

A solitary difference from its close analog exists: its `acquire` method's first argument is named *block*, as is consistent with **`Lock.acquire()`**.

Note

On macOS, `sem_timedwait` is unsupported, so calling `acquire()` with a timeout will emulate that function's behavior using a sleeping loop.

Note

If the SIGINT signal generated by `Ctrl-C` arrives while the main thread is blocked by a call to **`BoundedSemaphore.acquire()`**, **`Lock.acquire()`**, **`RLock.acquire()`**, **`Semaphore.acquire()`**,

`Condition.acquire()` or **`Condition.wait()`** then the call will be immediately interrupted and **`KeyboardInterrupt`** will be raised.

This differs from the behaviour of **`threading`** where SIGINT will be ignored while the equivalent blocking calls are in progress.

Note

Some of this package's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the **`multiprocessing.synchronize`** module will be disabled, and attempts to import it will result in an **`ImportError`**. See bpo-3770 [https://bugs.python.org/issue?@action=redirect&bpo=3770] for additional information.

Shared **`ctypes`** Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

multiprocessing.Value(*typecode_or_type*, **args*, *lock=True*)

Return a **`ctypes`** object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object. The object itself can be accessed via the *value* attribute of a **`Value`**.

typecode_or_type determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the **`array`** module. **args* is passed on to the constructor for the type.

If *lock* is `True` (the default) then a new recursive lock object is created to synchronize access to the value. If *lock* is a **`Lock`** or **`RLock`** object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Operations like `+=` which involve a read and write are not atomic. So if, for instance, you want to atomically increment a shared value it is insufficient to just do

```
counter.value += 1
```

Assuming the associated lock is recursive (which it is by default) you can instead do

```
with counter.get_lock():
    counter.value += 1
```

Note that *lock* is a keyword-only argument.

multiprocessing.Array(*typecode_or_type*, *size_or_initializer*, *, *lock=True*)

Return a ctypes array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

typecode_or_type determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the **array** module. If *size_or_initializer* is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a **Lock** or **RLock** object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that *lock* is a keyword only argument.

Note that an array of **ctypes.c_char** has *value* and *raw* attributes which allow one to use it to store and retrieve strings.

The `multiprocessing.sharedctypes` module

The `multiprocessing.sharedctypes` module provides functions for allocating `ctypes` objects from shared memory which can be inherited by child processes.

Note

Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the context of a second process and trying to dereference the pointer from the second process may cause a crash.

multiprocessing.sharedctypes.RawArray(*typecode_or_type*, *size_or_initializer*)

Return a ctypes array allocated from shared memory.

typecode_or_type determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the `array` module. If *size_or_initializer* is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use `Array()` instead to make sure that access is automatically synchronized using a lock.

multiprocessing.sharedctypes.RawValue(*typecode_or_type*, **args*)

Return a ctypes object allocated from shared memory.

typecode_or_type determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the `array` module. **args* is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic – use **`Value()`** instead to make sure that access is automatically synchronized using a lock.

Note that an array of **`ctypes.c_char`** has `value` and `raw` attributes which allow one to use it to store and retrieve strings – see documentation for **`ctypes`**.

multiprocessing.sharedctypes.Array(*typecode_or_type*, *size_or_initializer*, *, *lock=True*)

The same as **`RawArray()`** except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a **`Lock`** or **`RLock`** object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Note that *lock* is a keyword-only argument.

multiprocessing.sharedctypes.Value(*typecode_or_type*, **args*, *lock=True*)

The same as **`RawValue()`** except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a **`Lock`** or **`RLock`** object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Note that *lock* is a keyword-only argument.

multiprocessing.sharedctypes.copy(*obj*)

Return a ctypes object allocated from shared memory which is a copy of the ctypes object *obj*.

multiprocessing.sharedctypes.synchronized(*obj*[, *lock*])

Return a process-safe wrapper object for a ctypes object which uses *lock* to synchronize access. If *lock* is `None` (the default) then a **`multiprocessing.RLock`** object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps: **`get_obj()`** returns the wrapped object and **`get_lock()`** returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

Changed in version 3.5: Synchronized objects support the context manager protocol.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table `MyStruct` is some subclass of **`ctypes.Structure`**.)

ctypes	sharedctypes using typecode
Value(c_double, 2.4)	RawValue(c_double, 2.4)
Value(MyStruct, 4, 6)	RawValue(MyStruct, 4, 6)
Array(c_int, 7)	RawArray(c_int, 7)
Array(c_int, [1, 2, 3])	RawArray(c_int, [1, 2, 3])

Below is an example where a number of ctypes objects are modified by a child process:

```
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]
```

```
def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', b'hello world', lock=lock)
    A = Array(Point, [(1.875,-6.25), (-5.75,2.0), (2.375

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()

    print(n.value)
    print(x.value)
    print(s.value)
    print([(a.x, a.y) for a in A])
```

The results printed are

```
49
0.1111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.25)]
```

Managers

Managers provide a way to create data which can be shared between different processes, including sharing over a network between processes running on different machines. A manager object controls a server process which manages *shared objects*. Other processes can access the shared objects by using proxies.

multiprocessing.Manager()

Returns a started **SyncManager** object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the **multiprocessing.managers** module:

class multiprocessing.managers.BaseManager(*address=None*, *authkey=None*, *serializer='pickle'*, *ctx=None*, ***, *shutdown_timeout=1.0*)

Create a BaseManager object.

Once created one should call **start()** or `get_server().serve_forever()` to ensure that the manager object refers to a started manager process.

address is the address on which the manager process listens for new connections. If *address* is `None` then an arbitrary one is chosen.

authkey is the authentication key which will be used to check the validity of incoming connections to the server process. If *authkey* is `None` then `current_process().authkey` is used. Otherwise *authkey* is used and it must be a byte string.

serializer must be `'pickle'` (use **pickle** serialization) or `'xmlrpclib'` (use **xmlrpc.client** serialization).

ctx is a context object, or `None` (use the current context). See the **get_context()** function.

shutdown_timeout is a timeout in seconds used to wait until the process used by the manager completes in the **shutdown()** method. If the shutdown times out, the process is terminated. If terminating the process also times out, the process is killed.

Changed in version 3.11: Added the *shutdown_timeout* parameter.

start([*initializer*[, *initargs*]])

Start a subprocess to start the manager. If *initializer* is not `None` then the subprocess will call `initializer(*initargs)` when it starts.

get_server()

Returns a **`Server`** object which represents the actual server under the control of the Manager. The **`Server`** object supports the **`serve_forever()`** method:

```
>>> from multiprocessing.managers import BaseMa
>>> manager = BaseManager(address=('', 50000),
>>> server = manager.get_server()
>>> server.serve_forever()
```

`Server` additionally has an **`address`** attribute.

connect()

Connect a local manager object to a remote manager process:

```
>>> from multiprocessing.managers import BaseMa
>>> m = BaseManager(address=('127.0.0.1', 5000
>>> m.connect()
```

shutdown()

Stop the process used by the manager. This is only available if **`start()`** has been used to start the server process.

This can be called multiple times.

register(*typeid*[, *callable*[, *proxytype*[, *exposed*[, *method_to_typeid*[, *create_method*]]]]])

A classmethod which can be used for registering a type or callable with the manager class.

typeid is a “type identifier” which is used to identify a particular type of shared object. This must be a string.

callable is a callable used for creating objects for this type identifier. If a manager instance will be connected to the server using the **`connect()`** method, or if the *create_method* argument is `False` then this can be left as `None`.

proxytype is a subclass of **`BaseProxy`** which is used to create proxies for shared objects with this *typeid*. If `None` then a proxy class is created automatically.

exposed is used to specify a sequence of method names which proxies for this typeid should be allowed to access using **`BaseProxy._callmethod()`**. (If *exposed* is `None` then **`proxytype._exposed_`** is used instead if it exists.) In the case where no exposed list is specified, all “public methods” of the shared object will be accessible. (Here a “public method” means any attribute which has a **`__call__()`** method and whose name does not begin with `'_'`.)

method_to_typeid is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If *method_to_typeid* is `None` then **`proxytype._method_to_typeid_`** is used instead if it exists.) If a method’s name is not a key of this mapping or if the mapping is `None` then the object returned by the method will be copied by value.

create_method determines whether a method should be created with name *typeid* which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is `True`.

`BaseManager` instances also have one read-only property:

address

The address used by the manager.

Changed in version 3.3: Manager objects support the context management protocol – see Context Manager Types. **`__enter__()`** starts the server process (if it has not already started) and then returns the manager object. **`__exit__()`** calls **`shutdown()`**.

In previous versions **`__enter__()`** did not start the manager's server process if it was not already started.

class multiprocessing.managers.SyncManager

A subclass of **`BaseManager`** which can be used for the synchronization of processes. Objects of this type are returned by **`multiprocessing.Manager()`**.

Its methods create and return Proxy Objects for a number of commonly used data types to be synchronized across processes. This notably includes shared lists and dictionaries.

Barrier(*parties*[, *action*[, *timeout*]])

Create a shared **`threading.Barrier`** object and return a proxy for it.

New in version 3.3.

BoundedSemaphore([*value*])

Create a shared **`threading.BoundedSemaphore`** object and return a proxy for it.

Condition([*lock*])

Create a shared **`threading.Condition`** object and return a proxy for it.

If *lock* is supplied then it should be a proxy for a **`threading.Lock`** or **`threading.RLock`** object.

Changed in version 3.3: The **`wait_for()`** method was added.

Event()

Create a shared **`threading.Event`** object and return a proxy for it.

Lock()

Create a shared **`threading.Lock`** object and return a proxy for it.

Namespace()

Create a shared **`Namespace`** object and return a proxy for it.

Queue([*maxsize*])

Create a shared **`queue.Queue`** object and return a proxy for it.

RLock()

Create a shared **`threading.RLock`** object and return a proxy for it.

Semaphore([*value*])

Create a shared **`threading.Semaphore`** object and return a proxy for it.

Array(*typecode*, *sequence*)

Create an array and return a proxy for it.

Value(*typecode*, *value*)

Create an object with a writable `value` attribute and return a proxy for it.

dict()

dict(*mapping*)
dict(*sequence*)
: Create a shared **dict** object and return a proxy for it.

list()
list(*sequence*)
: Create a shared **list** object and return a proxy for it.

Changed in version 3.6: Shared objects are capable of being nested. For example, a shared container object such as a shared list can contain other shared objects which will all be managed and synchronized by the **SyncManager**.

class multiprocessing.managers.Namespace
: A type that can register with **SyncManager**.

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with `'_'` will be an attribute of the proxy and not an attribute of the referent:

```
>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3    # this is an attribute of t
>>> print(Global)
Namespace(x=10, y='hello')
```

Customized managers

To create one's own manager, one creates a subclass of **BaseManager** and uses the **register()** classmethod to register new types or callables with the manager class. For example:

```
from multiprocessing.managers import BaseManager

class MathsClass:
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass

MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    with MyManager() as manager:
        maths = manager.Maths()
        print(maths.add(4, 3))         # prints 7
        print(maths.mul(7, 8))         # prints 56
```

Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```
>>> from multiprocessing.managers import BaseManager
>>> from queue import Queue
>>> queue = Queue()
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda:q
>>> m = QueueManager(address=('', 50000), authkey=b'abra
>>> s = m.get_server()
>>> s.serve_forever()
```

One client can access the server as follows:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), aut
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), aut
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'
```

Local processes can also access that queue, using the code from above on the client to access it remotely:

```
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...         super().__init__()
...     def run(self):
...         self.q.put('local hello')
...
>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()
>>> class QueueManager(BaseManager): pass
...
>>> QueueManager.register('get_queue', callable=lambda:
>>> m = QueueManager(address=('', 50000), authkey=b'abra
>>> s = m.get_server()
```

```
>>> s.serve_forever()
```

Proxy Objects

A proxy is an object which *refers* to a shared object which lives (presumably) in a different process. The shared object is said to be the *referent* of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). In this way, a proxy can be used just like its referent can:

```
>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print(l)
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print(repr(l))
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]
```

Notice that applying **`str()`** to a proxy will return the representation of the referent, whereas applying **`repr()`** will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. As such, a referent can contain Proxy Objects. This permits nesting of these managed lists, dicts, and other Proxy Objects:

```
>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)         # referent of a now contains ref
>>> print(a, b)
[<ListProxy object, typeid 'list' at ...>] []
```

```
>>> b.append('hello')
>>> print(a[0], b)
['hello'] ['hello']
```

Similarly, dict and list proxies may be nested inside one another:

```
>>> l_outer = manager.list([ manager.dict() for i in ran
>>> d_first_inner = l_outer[0]
>>> d_first_inner['a'] = 1
>>> d_first_inner['b'] = 2
>>> l_outer[1]['c'] = 3
>>> l_outer[1]['z'] = 26
>>> print(l_outer[0])
{'a': 1, 'b': 2}
>>> print(l_outer[1])
{'c': 3, 'z': 26}
```

If standard (non-proxy) **`list`** or **`dict`** objects are contained in a referent, modifications to those mutable values will not be propagated through the manager because the proxy has no way of knowing when the values contained within are modified. However, storing a value in a container proxy (which triggers a `__setitem__` on the proxy object) does propagate through the manager and so to effectively modify such an item, one could re-assign the modified value to the container proxy:

```
# create a list proxy and append a mutable object (a dic
lproxy = manager.list()
lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
# at this point, the changes to d are not yet synced, bu
# updating the dictionary, the proxy is notified of the
lproxy[0] = d
```

This approach is perhaps less convenient than employing nested Proxy Objects for most use cases but also demonstrates a level of control over the synchronization.

Note

The proxy types in **multiprocessing** do nothing to support comparisons by value. So, for instance, we have:

```
>>> manager.list([1,2,3]) == [1,2,3]
False
```

One should just use a copy of the referent instead when making comparisons.

class multiprocessing.managers.BaseProxy

Proxy objects are instances of subclasses of **BaseProxy**.

_callmethod(*methodname*[, *args*[, *kwds*]])

Call and return the result of a method of the proxy's referent.

If `proxy` is a proxy whose referent is `obj` then the expression

```
proxy._callmethod(methodname, args, kwds)
```

will evaluate the expression

```
getattr(obj, methodname)(*args, **kwds)
```

in the manager's process.

The returned value will be a copy of the result of the call or a proxy to a new shared object – see documentation for the *method_to_typeid* argument of **BaseManager.register()**.

If an exception is raised by the call, then is re-raised by **_callmethod()**. If some other exception is raised in the manager's process then this is converted into a **RemoteError** exception and is raised by **_callmethod()**.

Note in particular that an exception will be raised if *methodname* has not been *exposed*.

An example of the usage of `_callmethod()`:

```
>>> l = manager.list(range(10))
>>> l._callmethod('__len__')
10
>>> l._callmethod('__getitem__', (slice(2, 7),))
[2, 3, 4, 5, 6]
>>> l._callmethod('__getitem__', (20,))
Traceback (most recent call last):
...
IndexError: list index out of range
```

_getvalue()

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

repr()

Return a representation of the proxy object.

str()

Return the representation of the referent.

Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

Process Pools

One can create a pool of processes which will carry out tasks submitted to it with the **`Pool`** class.

class multiprocessing.pool.Pool([*processes*[, *initializer*[, *initargs*[, *maxtasksperchild*[, *context*]]]]])

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

processes is the number of worker processes to use. If *processes* is `None` then the number returned by **`os.cpu_count()`** is used.

If *initializer* is not `None` then each worker process will call `initializer(*initargs)` when it starts.

maxtasksperchild is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default *maxtasksperchild* is `None`, which means worker processes will live as long as the pool.

context can be used to specify the context used for starting the worker processes. Usually a pool is created using the function **`multiprocessing.Pool()`** or the **`Pool()`** method of a context object. In both cases *context* is set appropriately.

Note that the methods of the pool object should only be called by the process which created the pool.

Warning

`multiprocessing.pool` objects have internal resources that need to be properly managed (like any other resource) by using the pool as a context manager or by calling **`close()`** and **`terminate()`** manually. Failure to do this can lead to the process hanging on finalization.

Note that it is **not correct** to rely on the garbage collector to destroy the pool as CPython does not assure that the

finalizer of the pool will be called (see **object.__del__()** for more information).

New in version 3.2: maxtasksperchild

New in version 3.4: context

Note

Worker processes within a **Pool** typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, mod_wsgi, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The *maxtasksperchild* argument to the **Pool** exposes this ability to the end user.

apply(*func*[, *args*[, *kwds*]])

Call *func* with arguments *args* and keyword arguments *kwds*. It blocks until the result is ready. Given this blocks, **apply_async()** is better suited for performing work in parallel. Additionally, *func* is only executed in one of the workers of the pool.

apply_async(*func*[, *args*[, *kwds*[, *callback*[, *error_callback*]]]])

A variant of the **apply()** method which returns a **AsyncResult** object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error_callback* is applied instead.

If *error_callback* is specified then it should be a callable which accepts a single argument. If the target function

fails, then the *error_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

map(*func*, *iterable*[, *chunksize*])

A parallel equivalent of the **`map()`** built-in function (it supports only one *iterable* argument though, for multiple iterables see **`starmap()`**). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer.

Note that it may cause high memory usage for very long iterables. Consider using **`imap()`** or **`imap_unordered()`** with explicit *chunksize* option for better efficiency.

map_async(*func*, *iterable*[, *chunksize*[, *callback*[, *error_callback*]]])

A variant of the **`map()`** method which returns a **`AsyncResult`** object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error_callback* is applied instead.

If *error_callback* is specified then it should be a callable which accepts a single argument. If the target function fails, then the *error_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise

the thread which handles the results will get blocked.

imap(*func*, *iterable*[, *chunksize*])

A lazier version of **`map()`**.

The *chunksize* argument is the same as the one used by the **`map()`** method. For very long iterables using a large value for *chunksize* can make the job complete **much** faster than using the default value of `1`.

Also if *chunksize* is `1` then the **`next()`** method of the iterator returned by the **`imap()`** method has an optional *timeout* parameter: `next(timeout)` will raise **`multiprocessing.TimeoutError`** if the result cannot be returned within *timeout* seconds.

imap_unordered(*func*, *iterable*[, *chunksize*])

The same as **`imap()`** except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be “correct”.)

starmap(*func*, *iterable*[, *chunksize*])

Like **`map()`** except that the elements of the *iterable* are expected to be iterables that are unpacked as arguments.

Hence an *iterable* of `[(1,2), (3, 4)]` results in `[func(1,2), func(3,4)]`.

New in version 3.3.

starmap_async(*func*, *iterable*[, *chunksize*[, *callback*[, *error_callback*]]])

A combination of **`starmap()`** and **`map_async()`** that iterates over *iterable* of iterables and calls *func* with the iterables unpacked. Returns a result object.

New in version 3.3.

close()

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

terminate()

Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected **`terminate()`** will be called immediately.

join()

Wait for the worker processes to exit. One must call **`close()`** or **`terminate()`** before using **`join()`**.

New in version 3.3: Pool objects now support the context management protocol – see Context Manager Types. **`__enter__()`** returns the pool object, and **`__exit__()`** calls **`terminate()`**.

class multiprocessing.pool.AsyncResult

The class of the result returned by **`Pool.apply_async()`** and **`Pool.map_async()`**.

get([*timeout*])

Return the result when it arrives. If *timeout* is not `None` and the result does not arrive within *timeout* seconds then **`multiprocessing.TimeoutError`** is raised. If the remote call raised an exception then that exception will be reraised by **`get()`**.

wait([*timeout*])

Wait until the result is available or until *timeout* seconds pass.

ready()

Return whether the call has completed.

successful()

Return whether the call completed without raising an exception. Will raise **ValueError** if the result is not ready.

Changed in version 3.7: If the result is not ready, **ValueError** is raised instead of **AssertionError**.

The following example demonstrates the use of a pool:

```
from multiprocessing import Pool
import time

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(processes=4) as pool:          # start 4 wo
        result = pool.apply_async(f, (10,)) # evaluate "
        print(result.get(timeout=1))         # prints "10

        print(pool.map(f, range(10)))        # prints "[0

        it = pool.imap(f, range(10))
        print(next(it))                      # prints "0"
        print(next(it))                      # prints "1"
        print(it.next(timeout=1))            # prints "4"

        result = pool.apply_async(time.sleep, (10,))
        print(result.get(timeout=1))         # raises mul
```

Listeners and Clients

Usually message passing between processes is done using queues or by using **Connection** objects returned by **Pipe()**.

However, the **multiprocessing.connection** module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes. It also has support for *digest authentication* using the **hmac** module, and for polling multiple connections at the same time.

multiprocessing.connection.deliver_challenge(*connection*, *authkey*)

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using *authkey* as the key then a welcome message is sent to the other end of the connection. Otherwise **AuthenticationError** is raised.

multiprocessing.connection.answer_challenge(*connection*, *authkey*)

Receive a message, calculate the digest of the message using *authkey* as the key, and then send the digest back.

If a welcome message is not received, then **AuthenticationError** is raised.

multiprocessing.connection.Client(*address*[, *family*[, *authkey*]])

Attempt to set up a connection to the listener which is using address *address*, returning a **Connection**.

The type of the connection is determined by *family* argument, but this can generally be omitted since it can usually be inferred from the format of *address*. (See Address Formats)

If *authkey* is given and not None, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is None. **AuthenticationError** is raised if authentication fails. See Authentication keys.

class multiprocessing.connection.Listener([*address*[, *family*[, *backlog*[, *authkey*]]]])

A wrapper for a bound socket or Windows named pipe which is ‘listening’ for connections.

address is the address to be used by the bound socket or named pipe of the listener object.

Note

If an address of ‘0.0.0.0’ is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use ‘127.0.0.1’.

family is the type of socket (or named pipe) to use. This can be one of the strings `'AF_INET'` (for a TCP socket), `'AF_UNIX'` (for a Unix domain socket) or `'AF_PIPE'` (for a Windows named pipe). Of these only the first is guaranteed to be available. If *family* is `None` then the family is inferred from the format of *address*. If *address* is also `None` then a default is chosen. This default is the family which is assumed to be the fastest available. See Address Formats. Note that if *family* is `'AF_UNIX'` and address is `None` then the socket will be created in a private temporary directory created using **`tempfile.mkstemp()`**.

If the listener object uses a socket then *backlog* (1 by default) is passed to the **`listen()`** method of the socket once it has been bound.

If *authkey* is given and not None, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is None. **`AuthenticationError`** is raised if authentication fails. See Authentication keys.

accept()

Accept a connection on the bound socket or named pipe of the listener object and return a **`Connection`** object. If authentication is attempted and fails, then **`AuthenticationError`** is raised.

close()

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

address

The address which is being used by the Listener object.

last_accepted

The address from which the last accepted connection came. If this is unavailable then it is `None`.

New in version 3.3: Listener objects now support the context management protocol – see Context Manager Types. **`__enter__()`** returns the listener object, and **`__exit__()`** calls **`close()`**.

multiprocessing.connection.wait(*object_list*, *timeout*=*None*)

Wait till an object in *object_list* is ready. Returns the list of those objects in *object_list* which are ready. If *timeout* is a float then the call blocks for at most that many seconds. If *timeout* is `None` then it will block for an unlimited period. A negative timeout is equivalent to a zero timeout.

For both Unix and Windows, an object can appear in *object_list* if it is

- a readable **`Connection`** object;
- a connected and readable **`socket.socket`** object; or
- the **`sentinel`** attribute of a **`Process`** object.

A connection or socket object is ready when there is data available to be read from it, or the other end has been closed.

Unix: `wait(object_list, timeout)` almost equivalent `select.select(object_list, [], [], timeout)`.

The difference is that, if **`select.select()`** is interrupted by a signal, it can raise **`OSError`** with an error number of `EINTR`, whereas **`wait()`** will not.

Windows: An item in *object_list* must either be an integer handle which is waitable (according to the definition used by the documentation of the Win32 function `WaitForMultipleObjects()`) or it can be an object with a **`fileno()`** method which returns a socket handle or pipe handle. (Note that pipe handles and socket handles are **not** waitable handles.)

New in version 3.3.

Examples

The following server code creates a listener which uses `'secret password'` as an authentication key. It then waits for a connection and sends some data to the client:

```
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)     # family is deduced to

with Listener(address, authkey=b'secret password') as li
    with listener.accept() as conn:
        print('connection accepted from', listener.last_

        conn.send([2.25, None, 'junk', float])

        conn.send_bytes(b'hello')

        conn.send_bytes(array('i', [42, 1729]))
```

The following code connects to the server and receives some data from the server:

```
from multiprocessing.connection import Client
from array import array
```

```
address = ('localhost', 6000)

with Client(address, authkey=b'secret password') as conn
    print(conn.recv())                  # => [2.25, None

    print(conn.recv_bytes())            # => 'hello'

    arr = array('i', [0, 0, 0, 0, 0])
    print(conn.recv_bytes_into(arr))    # => 8
    print(arr)                          # => array('i',
```

The following code uses **`wait()`** to wait for messages from multiple processes at once:

```
import time, random
from multiprocessing import Process, Pipe, current_proce
from multiprocessing.connection import wait

def foo(w):
    for i in range(10):
        w.send((i, current_process().name))
    w.close()

if __name__ == '__main__':
    readers = []

    for i in range(4):
        r, w = Pipe(duplex=False)
        readers.append(r)
        p = Process(target=foo, args=(w,))
        p.start()
        # We close the writable end of the pipe now to b
        # p is the only process which owns a handle for
        # ensures that when p closes its handle for the
        # wait() will promptly report the readable end a
        w.close()

    while readers:
```

```
        for r in wait(readers):
            try:
                msg = r.recv()
            except EOFError:
                readers.remove(r)
            else:
                print(msg)
```

Address Formats

- An `'AF_INET'` address is a tuple of the form `(hostname, port)` where *hostname* is a string and *port* is an integer.
- An `'AF_UNIX'` address is a string representing a filename on the filesystem.
- An `'AF_PIPE'` address is a string of the form `r'\\.\pipe\`*`PipeName`*`'`. To use **`Client()`** to connect to a named pipe on a remote computer called *ServerName* one should use an address of the form `r'\\`*`ServerName`*`\pipe\`*`PipeName`*`'` instead.

Note that any string beginning with two backslashes is assumed by default to be an `'AF_PIPE'` address rather than an `'AF_UNIX'` address.

Authentication keys

When one uses **`Connection.recv`**, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore **`Listener`** and **`Client()`** use the **`hmac`** module to provide digest authentication.

An authentication key is a byte string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but no authentication key is specified then the return value of `current_process().authkey` is used (see **`Process`**). This value will be automatically inherited by any

Process object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using **os.urandom()**.

Logging

Some support for logging is available. Note, however, that the **logging** package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

multiprocessing.get_logger()

> Returns the logger used by **multiprocessing**. If necessary, a new one will be created.
>
> When first created the logger has level **logging.NOTSET** and no default handler. Messages sent to this logger will not by default propagate to the root logger.
>
> Note that on Windows child processes will only inherit the level of the parent process's logger – any other customization of the logger will not be inherited.

multiprocessing.log_to_stderr(*level=None*)

> This function performs a call to **get_logger()** but in addition to returning the logger created by get_logger, it adds a handler which sends output to **sys.stderr** using format `'[%(levelname)s/%(processName)s] %(message)s'`. You can modify `levelname` of the logger by passing a `level` argument.

Below is an example session with logging turned on:

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
```

```
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pymp-
[INFO/SyncManager-...] manager serving at '/.../listener
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-...] manager exiting with exitcode 0
```

For a full table of logging levels, see the **`logging`** module.

The **`multiprocessing.dummy`** module

`multiprocessing.dummy` replicates the API of **`multiprocessing`** but is no more than a wrapper around the **`threading`** module.

In particular, the `Pool` function provided by **`multiprocessing.dummy`** returns an instance of **`ThreadPool`**, which is a subclass of **`Pool`** that supports all the same method calls but uses a pool of worker threads rather than worker processes.

class multiprocessing.pool.ThreadPool([*processes*[, *initializer*[, *initargs*]]])

> A thread pool object which controls a pool of worker threads to which jobs can be submitted. **`ThreadPool`** instances are fully interface compatible with **`Pool`** instances, and their resources must also be properly managed, either by using the pool as a context manager or by calling **`close()`** and **`terminate()`** manually.
>
> *processes* is the number of worker threads to use. If *processes* is `None` then the number returned by **`os.cpu_count()`** is used.
>
> If *initializer* is not `None` then each worker process will call `initializer(*initargs)` when it starts.

Unlike `Pool`, *maxtasksperchild* and *context* cannot be provided.

Note

A `ThreadPool` shares the same interface as `Pool`, which is designed around a pool of processes and predates the introduction of the `concurrent.futures` module. As such, it inherits some operations that don't make sense for a pool backed by threads, and it has its own type for representing the status of asynchronous jobs, `AsyncResult`, that is not understood by any other libraries.

Users should generally prefer to use `concurrent.futures.ThreadPoolExecutor`, which has a simpler interface that was designed around threads from the start, and which returns `concurrent.futures.Future` instances that are compatible with many other libraries, including `asyncio`.

Programming guidelines

There are certain guidelines and idioms which should be adhered to when using `multiprocessing`.

All start methods

The following applies to all start methods.

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the *same* proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or `active_children()` is called) all completed processes which have not yet been joined will be joined. Also calling a finished process's `Process.is_alive` will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

When using the *spawn* or *forkserver* start methods many types from `multiprocessing` need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the **`Process.terminate`** method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using **`Process.terminate`** on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the “feeder” thread to the underlying pipe. (The child process can call the **`Queue.cancel_join_thread`** method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following:

```
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()                    # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix using the *fork* start method, a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows and the other start methods this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

should be rewritten as

```
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
```

```
    for i in range(10):
        Process(target=f, args=(lock,)).start()
```

Beware of replacing **sys.stdin** with a “file like object”

> **multiprocessing** originally unconditionally called:
>
> ```
> os.close(sys.stdin.fileno())
> ```
>
> in the **multiprocessing.Process._bootstrap()** method — this resulted in issues with processes-in-processes. This has been changed to:
>
> ```
> sys.stdin.close()
> sys.stdin = open(os.open(os.devnull, os.O_RDONLY),
> ```
>
> Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace **sys.stdin()** with a “file-like object” with output buffering. This danger is that if multiple processes call **close()** on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.
>
> If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:
>
> ```
> @property
> def cache(self):
>     pid = os.getpid()
>     if pid != self._pid:
>         self._pid = pid
>         self._cache = []
>     return self._cache
> ```

For more information, see bpo-5155 [https://bugs.python.org/issue?@action=redirect&bpo=5155], bpo-5313 [https://bugs.python.org/issue?@action=redirect&bpo=5313] and bpo-5331 [https://bugs.python.org/issue?@action=redirect&bpo=5331]

The *spawn* and *forkserver* start methods

There are a few extra restriction which don't apply to the *fork* start method.

More picklability

> Ensure that all arguments to **`Process.__init__()`** are picklable. Also, if you subclass **`Process`** then make sure that instances will be picklable when the **`Process.start`** method is called.

Global variables

> Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that **`Process.start`** was called.
>
> However, global variables which are just module level constants cause no problems.

Safe importing of main module

> Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such a starting a new process).
>
> For example, using the *spawn* or *forkserver* start method running the following module would fail with a **`RuntimeError`**:

```
from multiprocessing import Process

def foo():
    print('hello')

p = Process(target=foo)
p.start()
```

Instead one should protect the “entry point” of the program by using `if __name__ == '__main__':` as follows:

```
from multiprocessing import Process, freeze_suppor

def foo():
    print('hello')

if __name__ == '__main__':
    freeze_support()
    set_start_method('spawn')
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module’s `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.

Examples

Demonstration of how to create and use customized managers and proxies:

```
from multiprocessing import freeze_support
```

```
from multiprocessing.managers import BaseManager, BasePr
import operator

##

class Foo:
    def f(self):
        print('you called Foo.f()')
    def g(self):
        print('you called Foo.g()')
    def _h(self):
        print('you called Foo._h()')

# A simple generator function
def baz():
    for i in range(10):
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ['__next__']
    def __iter__(self):
        return self
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module
def get_operator_module():
    return operator

##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessibl
MyManager.register('Foo1', Foo)
```

```
# register the Foo class; make `g()` and `_h()` accessib
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorPro
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print('-' * 20)

    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

    print('-' * 20)

    f2 = manager.Foo2()
    f2.g()
    f2._h()
    assert not hasattr(f2, 'f')
    assert sorted(f2._exposed_) == sorted(['g', '_h'])

    print('-' * 20)

    it = manager.baz()
    for i in it:
        print('<%d>' % i, end=' ')
    print()
```

```
    print('-' * 20)

    op = manager.operator()
    print('op.add(23, 45) =', op.add(23, 45))
    print('op.pow(2, 94) =', op.pow(2, 94))
    print('op._exposed_ =', op._exposed_)

##

if __name__ == '__main__':
    freeze_support()
    test()
```

Using `Pool`:

```
import multiprocessing
import time
import random
import sys

#
# Functions used by test code
#

def calculate(func, args):
    result = func(*args)
    return '%s says that %s%s = %s' % (
        multiprocessing.current_process().name,
        func.__name__, args, result
        )

def calculatestar(args):
    return calculate(*args)

def mul(a, b):
    time.sleep(0.5 * random.random())
    return a * b

def plus(a, b):
```

```
    time.sleep(0.5 * random.random())
    return a + b

def f(x):
    return 1.0 / (x - 5.0)

def pow3(x):
    return x ** 3

def noop(x):
    pass

#
# Test code
#

def test():
    PROCESSES = 4
    print('Creating pool with %d processes\n' % PROCESSE

    with multiprocessing.Pool(PROCESSES) as pool:

        print()

if __name__ == '__main__':
    multiprocessing.freeze_support()
    test()
```

An example showing how to use queues to feed tasks to a collection of worker processes and collect the results:

```
import time
import random

from multiprocessing import Process, Queue, current_proc

#
# Function run by worker processes
#

def worker(input, output):
    for func, args in iter(input.get, 'STOP'):
        result = calculate(func, args)
        output.put(result)

#
# Function used to calculate result
#

def calculate(func, args):
    result = func(*args)
```

```
    return '%s says that %s%s = %s' % \
        (current_process().name, func.__name__, args, re

#
# Functions referenced by tasks
#

def mul(a, b):
    time.sleep(0.5*random.random())
    return a * b

def plus(a, b):
    time.sleep(0.5*random.random())
    return a + b

#
#
#

def test():
    NUMBER_OF_PROCESSES = 4
    TASKS1 = [(mul, (i, 7)) for i in range(20)]
    TASKS2 = [(plus, (i, 8)) for i in range(10)]

    # Create queues
    task_queue = Queue()
    done_queue = Queue()

    # Submit tasks
    for task in TASKS1:
        task_queue.put(task)

    # Start worker processes
    for i in range(NUMBER_OF_PROCESSES):
        Process(target=worker, args=(task_queue, done_qu

    # Get and print results
    print('Unordered results:')
```

```
    for i in range(len(TASKS1)):
        print('\t', done_queue.get())

    # Add more tasks using `put()`
    for task in TASKS2:
        task_queue.put(task)

    # Get and print some more results
    for i in range(len(TASKS2)):
        print('\t', done_queue.get())

    # Tell child processes to stop
    for i in range(NUMBER_OF_PROCESSES):

if __name__ == '__main__':
    freeze_support()
    test()
```

multiprocessing.shared_memor — Shared memory for direct access across processes

Source code: Lib/multiprocessing/shared_memory.py [https://github.com/python/cpython/tree/3.11/Lib/multiprocessing/shared_memory.py]

New in version 3.8.

This module provides a class, **SharedMemory**, for the allocation and management of shared memory to be accessed by one or more processes on a multicore or symmetric multiprocessor (SMP) machine. To assist with the life-cycle management of shared memory especially across distinct processes, a **BaseManager** subclass, **SharedMemoryManager**, is also provided in the `multiprocessing.managers` module.

In this module, shared memory refers to "System V style" shared memory blocks (though is not necessarily implemented explicitly as such) and does not refer to "distributed shared memory". This style of shared memory permits distinct processes to potentially read and write to a common (or shared) region of volatile memory. Processes are conventionally limited to only have access to their own process memory space but shared memory permits the sharing of data between processes, avoiding the need to instead send messages between processes containing that data. Sharing data directly via memory can provide significant performance benefits compared to sharing data via disk or socket or other communications requiring the serialization/deserialization and copying of data.

class multiprocessing.shared_memory.SharedMemory(*name=None*, *create=False*, *size=0*)

Creates a new shared memory block or attaches to an existing

shared memory block. Each shared memory block is assigned a unique name. In this way, one process can create a shared memory block with a particular name and a different process can attach to that same shared memory block using that same name.

As a resource for sharing data across processes, shared memory blocks may outlive the original process that created them. When one process no longer needs access to a shared memory block that might still be needed by other processes, the `close()` method should be called. When a shared memory block is no longer needed by any process, the `unlink()` method should be called to ensure proper cleanup.

name is the unique name for the requested shared memory, specified as a string. When creating a new shared memory block, if `None` (the default) is supplied for the name, a novel name will be generated.

create controls whether a new shared memory block is created (`True`) or an existing shared memory block is attached (`False`).

size specifies the requested number of bytes when creating a new shared memory block. Because some platforms choose to allocate chunks of memory based upon that platform's memory page size, the exact size of the shared memory block may be larger or equal to the size requested. When attaching to an existing shared memory block, the `size` parameter is ignored.

close()

Closes access to the shared memory from this instance. In order to ensure proper cleanup of resources, all instances should call `close()` once the instance is no longer needed. Note that calling `close()` does not cause the shared memory block itself to be destroyed.

unlink()

Requests that the underlying shared memory block be

destroyed. In order to ensure proper cleanup of resources, `unlink()` should be called once (and only once) across all processes which have need for the shared memory block. After requesting its destruction, a shared memory block may or may not be immediately destroyed and this behavior may differ across platforms. Attempts to access data inside the shared memory block after `unlink()` has been called may result in memory access errors. Note: the last process relinquishing its hold on a shared memory block may call `unlink()` and **`close()`** in either order.

buf

A memoryview of contents of the shared memory block.

name

Read-only access to the unique name of the shared memory block.

size

Read-only access to size in bytes of the shared memory block.

The following example demonstrates low-level use of **`SharedMemory`** instances:

```
>>> from multiprocessing import shared_memory
>>> shm_a = shared_memory.SharedMemory(create=True, size
>>> type(shm_a.buf)
<class 'memoryview'>
>>> buffer = shm_a.buf
>>> len(buffer)
10
>>> buffer[:4] = bytearray([22, 33, 44, 55])  # Modify m
>>> buffer[4] = 100                           # Modify s
>>> # Attach to an existing shared memory block
>>> shm_b = shared_memory.SharedMemory(shm_a.name)
>>> import array
```

```
>>> array.array('b', shm_b.buf[:5])  # Copy the data int
array('b', [22, 33, 44, 55, 100])
>>> shm_b.buf[:5] = b'howdy'  # Modify via shm_b using b
>>> bytes(shm_a.buf[:5])      # Access via shm_a
b'howdy'
>>> shm_b.close()   # Close each SharedMemory instance
>>> shm_a.close()
>>> shm_a.unlink()  # Call unlink only once to release t
```

The following example demonstrates a practical use of the **`SharedMemory`** class with NumPy arrays [https://numpy.org/], accessing the same `numpy.ndarray` from two distinct Python shells:

```
>>> # In the first Python interactive shell
>>> import numpy as np
>>> a = np.array([1, 1, 2, 3, 5, 8])  # Start with an ex
>>> from multiprocessing import shared_memory
>>> shm = shared_memory.SharedMemory(create=True, size=a
>>> # Now create a NumPy array backed by shared memory
>>> b = np.ndarray(a.shape, dtype=a.dtype, buffer=shm.bu
>>> b[:] = a[:]  # Copy the original data into shared me
>>> b
array([1, 1, 2, 3, 5, 8])
>>> type(b)
<class 'numpy.ndarray'>
>>> type(a)
<class 'numpy.ndarray'>
>>> shm.name  # We did not specify a name so one was cho
'psm_21467_46075'

>>> # In either the same shell or a new Python shell on
>>> import numpy as np
>>> from multiprocessing import shared_memory
>>> # Attach to the existing shared memory block
>>> existing_shm = shared_memory.SharedMemory(name='psm_
>>> # Note that a.shape is (6,) and a.dtype is np.int64
>>> c = np.ndarray((6,), dtype=np.int64, buffer=existing
>>> c
```

```
array([1, 1, 2, 3, 5, 8])
>>> c[-1] = 888
>>> c
array([  1,   1,   2,   3,   5, 888])

>>> # Back in the first Python interactive shell, b refl
>>> b
array([  1,   1,   2,   3,   5, 888])

>>> # Clean up from within the second Python shell
>>> del c  # Unnecessary; merely emphasizing the array i
>>> existing_shm.close()

>>> # Clean up from within the first Python shell
>>> del b  # Unnecessary; merely emphasizing the array i
>>> shm.close()
>>> shm.unlink()  # Free and release the shared memory b
```

class multiprocessing.managers.SharedMemoryManager([*address*[, *authkey*]])

A subclass of **BaseManager** which can be used for the management of shared memory blocks across processes.

A call to **start()** on a **SharedMemoryManager** instance causes a new process to be started. This new process's sole purpose is to manage the life cycle of all shared memory blocks created through it. To trigger the release of all shared memory blocks managed by that process, call **shutdown()** on the instance. This triggers a **SharedMemory.unlink()** call on all of the **SharedMemory** objects managed by that process and then stops the process itself. By creating `SharedMemory` instances through a `SharedMemoryManager`, we avoid the need to manually track and trigger the freeing of shared memory resources.

This class provides methods for creating and returning **SharedMemory** instances and for creating a list-like object (**ShareableList**) backed by shared memory.

Refer to **multiprocessing.managers.BaseManager** for a description of the inherited *address* and *authkey* optional input arguments and how they may be used to connect to an existing `SharedMemoryManager` service from other processes.

SharedMemory(*size*)

Create and return a new **SharedMemory** object with the specified `size` in bytes.

ShareableList(*sequence*)

Create and return a new **ShareableList** object, initialized by the values from the input `sequence`.

The following example demonstrates the basic mechanisms of a **SharedMemoryManager**:

```
>>> from multiprocessing.managers import SharedMemoryMar
>>> smm = SharedMemoryManager()
>>> smm.start()  # Start the process that manages the sh
>>> sl = smm.ShareableList(range(4))
>>> sl
ShareableList([0, 1, 2, 3], name='psm_6572_7512')
>>> raw_shm = smm.SharedMemory(size=128)
>>> another_sl = smm.ShareableList('alpha')
>>> another_sl
ShareableList(['a', 'l', 'p', 'h', 'a'], name='psm_6572_
>>> smm.shutdown()  # Calls unlink() on sl, raw_shm, and
```

The following example depicts a potentially more convenient pattern for using **SharedMemoryManager** objects via the **with** statement to ensure that all shared memory blocks are released after they are no longer needed:

```
>>> with SharedMemoryManager() as smm:
...     sl = smm.ShareableList(range(2000))
...     # Divide the work among two processes, storing p
...     p1 = Process(target=do_work, args=(sl, 0, 1000))
...     p2 = Process(target=do_work, args=(sl, 1000, 200
```

```
...     p1.start()
...     p2.start()  # A multiprocessing.Pool might be mo
...     p1.join()
...     p2.join()   # Wait for all work to complete in b
...     total_result = sum(sl)  # Consolidate the partia
```

When using a **`SharedMemoryManager`** in a **`with`** statement, the shared memory blocks created using that manager are all released when the **`with`** statement's code block finishes execution.

class multiprocessing.shared_memory.ShareableList(*sequence=None*, **, name=None*)

Provides a mutable list-like object where all values stored within are stored in a shared memory block. This constrains storable values to only the `int`, `float`, `bool`, `str` (less than 10M bytes each), `bytes` (less than 10M bytes each), and `None` built-in data types. It also notably differs from the built-in `list` type in that these lists can not change their overall length (i.e. no append, insert, etc.) and do not support the dynamic creation of new **`ShareableList`** instances via slicing.

sequence is used in populating a new `ShareableList` full of values. Set to `None` to instead attach to an already existing `ShareableList` by its unique shared memory name.

name is the unique name for the requested shared memory, as described in the definition for **`SharedMemory`**. When attaching to an existing `ShareableList`, specify its shared memory block's unique name while leaving `sequence` set to `None`.

count(*value*)

Returns the number of occurrences of `value`.

index(*value*)

Returns first index position of `value`. Raises **`ValueError`** if `value` is not present.

format

Read-only attribute containing the **`struct`** packing format used by all currently stored values.

shm

The **`SharedMemory`** instance where the values are stored.

The following example demonstrates basic use of a **`ShareableList`** instance:

```
>>> from multiprocessing import shared_memory
>>> a = shared_memory.ShareableList(['howdy', b'HoWdY',
>>> [ type(entry) for entry in a ]
[<class 'str'>, <class 'bytes'>, <class 'float'>, <class
>>> a[2]
-273.154
>>> a[2] = -78.5
>>> a[2]
-78.5
>>> a[2] = 'dry ice'  # Changing data types is supported
>>> a[2]
'dry ice'
>>> a[2] = 'larger than previously allocated storage spa
Traceback (most recent call last):
  ...
ValueError: exceeds available storage for existing str
>>> a[2]
'dry ice'
>>> len(a)
7
>>> a.index(42)
6
>>> a.count(b'howdy')
0
>>> a.count(b'HoWdY')
1
>>> a.shm.close()
```

```
>>> a.shm.unlink()
>>> del a  # Use of a ShareableList after call to unlink
```

The following example depicts how one, two, or many processes may access the same **`ShareableList`** by supplying the name of the shared memory block behind it:

```
>>> b = shared_memory.ShareableList(range(5))          #
>>> c = shared_memory.ShareableList(name=b.shm.name)   #
>>> c
ShareableList([0, 1, 2, 3, 4], name='...')
>>> c[-1] = -999
>>> b[-1]
-999
>>> b.shm.close()
>>> c.shm.close()
>>> c.shm.unlink()
```

The following examples demonstrates that `ShareableList` (and underlying `SharedMemory`) objects can be pickled and unpickled if needed. Note, that it will still be the same shared object. This happens, because the deserialized object has the same unique name and is just attached to an existing object with the same name (if the object is still alive):

```
>>> import pickle
>>> from multiprocessing import shared_memory
>>> sl = shared_memory.ShareableList(range(10))
>>> list(sl)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]

>>> deserialized_sl = pickle.loads(pickle.dumps(sl))
>>> list(deserialized_sl)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]

>>> sl[0] = -1
>>> deserialized_sl[1] = -2
>>> list(sl)
[-1, -2, 2, 3, 4, 5, 6, 7, 8, 9]
>>> list(deserialized_sl)
```

```
[-1, -2, 2, 3, 4, 5, 6, 7, 8, 9]

>>> sl.shm.close()
>>> sl.shm.unlink()
```

The `concurrent` package

Currently, there is only one module in this package:

- **`concurrent.futures`** – Launching parallel tasks

`concurrent.futures` — Launching parallel tasks

New in version 3.2.

Source code: Lib/concurrent/futures/thread.py [https://github.com/python/cpython/tree/3.11/Lib/concurrent/futures/thread.py] and Lib/concurrent/futures/process.py [https://github.com/python/cpython/tree/3.11/Lib/concurrent/futures/process.py]

The `concurrent.futures` module provides a high-level interface for asynchronously executing callables.

The asynchronous execution can be performed with threads, using `ThreadPoolExecutor`, or separate processes, using `ProcessPoolExecutor`. Both implement the same interface, which is defined by the abstract `Executor` class.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Executor Objects

class concurrent.futures.Executor

An abstract class that provides methods to execute calls asynchronously. It should not be used directly, but through its concrete subclasses.

submit(*fn*, */*, **args*, ***kwargs*)

Schedules the callable, *fn*, to be

executed as `fn(*args, **kwargs)` and returns a **`Future`** object representing the execution of the callable.

```
with ThreadPoolExecutor(max_workers=1) as
    future = executor.submit(pow, 323, 12
    print(future.result())
```

map(*func*, **iterables*, *timeout*=*None*, *chunksize*=*1*)

Similar to **`map(func, *iterables)`** except:

- the *iterables* are collected immediately rather than lazily;
- *func* is executed asynchronously and several calls to *func* may be made concurrently.

The returned iterator raises a **`TimeoutError`** if **`__next__()`** is called and the result isn't available after *timeout* seconds from the original call to **`Executor.map()`**. *timeout* can be an int or a float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If a *func* call raises an exception, then that exception will be raised when its value is retrieved from the iterator.

When using **`ProcessPoolExecutor`**, this method chops *iterables* into a number of chunks which it submits to the pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer. For very long

iterables, using a large value for *chunksize* can significantly improve performance compared to the default size of 1. With **ThreadPoolExecutor**, *chunksize* has no effect.

Changed in version 3.5: Added the *chunksize* argument.

shutdown(*wait=True, *, cancel_futures=False*)

Signal the executor that it should free any resources that it is using when the currently pending futures are done executing. Calls to **Executor.submit()** and **Executor.map()** made after shutdown will raise **RuntimeError**.

If *wait* is `True` then this method will not return until all the pending futures are done executing and the resources associated with the executor have been freed. If *wait* is `False` then this method will return immediately and the resources associated with the executor will be freed when all pending futures are done executing. Regardless of the value of *wait*, the entire Python program will not exit until all pending futures are done executing.

If *cancel_futures* is `True`, this method will cancel all pending futures that the executor has not started running. Any futures that are completed or running won't be cancelled, regardless of the value of *cancel_futures*.

If both *cancel_futures* and *wait* are `True`, all futures that the executor has started running will be completed prior to this method returning. The remaining futures are cancelled.

You can avoid having to call this method explicitly if you use the **`with`** statement, which will shutdown the **`Executor`** (waiting as if **`Executor.shutdown()`** were called with *wait* set to `True`):

```
import shutil
with ThreadPoolExecutor(max_workers=4) as
    e.submit(shutil.copy, 'src1.txt', 'de
    e.submit(shutil.copy, 'src2.txt', 'de
    e.submit(shutil.copy, 'src3.txt', 'de
    e.submit(shutil.copy, 'src4.txt', 'de
```

Changed in version 3.9: Added *cancel_futures*.

ThreadPoolExecutor

`ThreadPoolExecutor` is an **`Executor`** subclass that uses a pool of threads to execute calls asynchronously.

Deadlocks can occur when the callable associated with a **`Future`** waits on the results of another **`Future`**. For example:

```
import time
def wait_on_b():
    time.sleep(5)
    print(b.result())  # b will never complete because i
    return 5

def wait_on_a():
    time.sleep(5)
```

```
    print(a.result())  # a will never complete because i
    return 6

executor = ThreadPoolExecutor(max_workers=2)
a = executor.submit(wait_on_b)
b = executor.submit(wait_on_a)
```

And:

```
def wait_on_future():
    f = executor.submit(pow, 5, 2)
    # This will never complete because there is only one
    # it is executing this function.
    print(f.result())

executor = ThreadPoolExecutor(max_workers=1)
executor.submit(wait_on_future)
```

class concurrent.futures.ThreadPoolExecutor(*max_workers=None*, *thread_name_prefix=''*, *initializer=None*, *initargs=()*)

An **`Executor`** subclass that uses a pool of at most *max_workers* threads to execute calls asynchronously.

All threads enqueued to `ThreadPoolExecutor` will be joined before the interpreter can exit. Note that the exit handler which does this is executed *before* any exit handlers added using `atexit`. This means exceptions in the main thread must be caught and handled in order to signal threads to exit gracefully. For this reason, it is recommended that `ThreadPoolExecutor` not be used for long-running tasks.

initializer is an optional callable that is called at the start of each worker thread; *initargs* is a tuple of arguments passed to the initializer. Should *initializer* raise an exception, all currently pending jobs will raise a **`BrokenThreadPool`**, as well as any attempt to submit more jobs to the pool.

Changed in version 3.5: If *max_workers* is `None` or not given, it will default to the number of processors on the machine,

multiplied by `5`, assuming that **`ThreadPoolExecutor`** is often used to overlap I/O instead of CPU work and the number of workers should be higher than the number of workers for **`ProcessPoolExecutor`**.

New in version 3.6: The *thread_name_prefix* argument was added to allow users to control the **`threading.Thread`** names for worker threads created by the pool for easier debugging.

Changed in version 3.7: Added the *initializer* and *initargs* arguments.

Changed in version 3.8: Default value of *max_workers* is changed to `min(32, os.cpu_count() + 4)`. This default value preserves at least 5 workers for I/O bound tasks. It utilizes at most 32 CPU cores for CPU bound tasks which release the GIL. And it avoids using very large resources implicitly on many-core machines.

ThreadPoolExecutor now reuses idle worker threads before starting *max_workers* worker threads too.

ThreadPoolExecutor Example

```
import concurrent.futures
import urllib.request

URLS = ['http://www.foxnews.com/',
        'http://www.cnn.com/',
        'http://europe.wsj.com/',
        'http://www.bbc.co.uk/',
        'http://some-made-up-domain.com/']

# Retrieve a single page and report the URL and contents
def load_url(url, timeout):
    with urllib.request.urlopen(url, timeout=timeout) as
        return conn.read()

# We can use a with statement to ensure threads are clea
```

```
with concurrent.futures.ThreadPoolExecutor(max_workers=5
    # Start the load operations and mark each future wit
    future_to_url = {executor.submit(load_url, url, 60):
    for future in concurrent.futures.as_completed(future
        url = future_to_url[future]
        try:
            data = future.result()
        except Exception as exc:
            print('%r generated an exception: %s' % (url
        else:
            print('%r page is %d bytes' % (url, len(data
```

ProcessPoolExecutor

The **ProcessPoolExecutor** class is an **Executor** subclass that uses a pool of processes to execute calls asynchronously. **ProcessPoolExecutor** uses the **multiprocessing** module, which allows it to side-step the Global Interpreter Lock but also means that only picklable objects can be executed and returned.

The `__main__` module must be importable by worker subprocesses. This means that **ProcessPoolExecutor** will not work in the interactive interpreter.

Calling **Executor** or **Future** methods from a callable submitted to a **ProcessPoolExecutor** will result in deadlock.

class concurrent.futures.ProcessPoolExecutor(*max_workers=None*, *mp_context=None*, *initializer=None*, *initargs=()*, *max_tasks_per_child=None*)

An **Executor** subclass that executes calls asynchronously using a pool of at most *max_workers* processes. If *max_workers* is `None` or not given, it will default to the number of processors on the machine. If *max_workers* is less than or equal to `0`, then a **ValueError** will be raised. On Windows, *max_workers* must be less than or equal to `61`. If it is not then **ValueError** will be raised. If *max_workers* is `None`, then the default chosen will be at most `61`, even if more processors are available. *mp_context* can be a multiprocessing context or

None. It will be used to launch the workers. If *mp_context* is `None` or not given, the default multiprocessing context is used.

initializer is an optional callable that is called at the start of each worker process; *initargs* is a tuple of arguments passed to the initializer. Should *initializer* raise an exception, all currently pending jobs will raise a **`BrokenProcessPool`**, as well as any attempt to submit more jobs to the pool.

max_tasks_per_child is an optional argument that specifies the maximum number of tasks a single process can execute before it will exit and be replaced with a fresh worker process. By default *max_tasks_per_child* is `None` which means worker processes will live as long as the pool. When a max is specified, the "spawn" multiprocessing start method will be used by default in absence of a *mp_context* parameter. This feature is incompatible with the "fork" start method.

Changed in version 3.3: When one of the worker processes terminates abruptly, a **`BrokenProcessPool`** error is now raised. Previously, behaviour was undefined but operations on the executor or its futures would often freeze or deadlock.

Changed in version 3.7: The *mp_context* argument was added to allow users to control the start_method for worker processes created by the pool.

Added the *initializer* and *initargs* arguments.

Changed in version 3.11: The *max_tasks_per_child* argument was added to allow users to control the lifetime of workers in the pool.

ProcessPoolExecutor Example

```
import concurrent.futures
import math

PRIMES = [
```

```
    112272535095293,
    112582705942171,
    112272535095293,
    115280095190773,
    115797848077099,
    1099726899285419]

def is_prime(n):
    if n < 2:
        return False
    if n == 2:
        return True
    if n % 2 == 0:
        return False

    sqrt_n = int(math.floor(math.sqrt(n)))
    for i in range(3, sqrt_n + 1, 2):
        if n % i == 0:
            return False
    return True

def main():
    with concurrent.futures.ProcessPoolExecutor() as exe
        for number, prime in zip(PRIMES, executor.map(is
            print('%d is prime: %s' % (number, prime))

if __name__ == '__main__':
    main()
```

Future Objects

The **`Future`** class encapsulates the asynchronous execution of a callable. **`Future`** instances are created by **`Executor.submit()`**.

class concurrent.futures.Future

> Encapsulates the asynchronous execution of a callable. **`Future`** instances are created by **`Executor.submit()`** and should not be created directly except for testing.

cancel()

Attempt to cancel the call. If the call is currently being executed or finished running and cannot be cancelled then the method will return `False`, otherwise the call will be cancelled and the method will return `True`.

cancelled()

Return `True` if the call was successfully cancelled.

running()

Return `True` if the call is currently being executed and cannot be cancelled.

done()

Return `True` if the call was successfully cancelled or finished running.

result(*timeout*=*None*)

Return the value returned by the call. If the call hasn't yet completed then this method will wait up to *timeout* seconds. If the call hasn't completed in *timeout* seconds, then a **`TimeoutError`** will be raised. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then **`CancelledError`** will be raised.

If the call raised an exception, this

method will raise the same exception.

exception(*timeout*=*None*)

Return the exception raised by the call. If the call hasn't yet completed then this method will wait up to *timeout* seconds. If the call hasn't completed in *timeout* seconds, then a **`TimeoutError`** will be raised. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then **`CancelledError`** will be raised.

If the call completed without raising, `None` is returned.

add_done_callback(*fn*)

Attaches the callable *fn* to the future. *fn* will be called, with the future as its only argument, when the future is cancelled or finishes running.

Added callables are called in the order that they were added and are always called in a thread belonging to the process that added them. If the callable raises an **`Exception`** subclass, it will be logged and ignored. If the callable raises a **`BaseException`** subclass, the behavior is undefined.

If the future has already completed or been cancelled, *fn* will be called immediately.

The following **Future** methods are meant for use in unit tests and **Executor** implementations.

set_running_or_notify_cancel()

This method should only be called by **Executor** implementations before executing the work associated with the **Future** and by unit tests.

If the method returns `False` then the **Future** was cancelled, i.e. **Future.cancel()** was called and returned `True`. Any threads waiting on the **Future** completing (i.e. through **as_completed()** or **wait()**) will be woken up.

If the method returns `True` then the **Future** was not cancelled and has been put in the running state, i.e. calls to **Future.running()** will return `True`.

This method can only be called once and cannot be called after **Future.set_result()** or **Future.set_exception()** have been called.

set_result(*result*)

Sets the result of the work associated with the **Future** to *result*.

This method should only be used by **Executor** implementations and unit tests.

Changed in version 3.8: This method raises **concurrent.futures.InvalidStateError**

if the **Future** is already done.

set_exception(*exception*)

Sets the result of the work associated with the **Future** to the **Exception** *exception*.

This method should only be used by **Executor** implementations and unit tests.

Changed in version 3.8: This method raises **concurrent.futures.InvalidStateError** if the **Future** is already done.

Module Functions

concurrent.futures.wait(*fs*, *timeout=None*, *return_when=ALL_COMPLETED*)

Wait for the **Future** instances (possibly created by different **Executor** instances) given by *fs* to complete. Duplicate futures given to *fs* are removed and will be returned only once. Returns a named 2-tuple of sets. The first set, named `done`, contains the futures that completed (finished or cancelled futures) before the wait completed. The second set, named `not_done`, contains the futures that did not complete (pending or running futures).

timeout can be used to control the maximum number of seconds to wait before returning. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

return_when indicates when this function should return. It must be one of the following constants:

Constant	Description
FIRST_COMPLETED	The function will return when any future finishes or is

cancelled.

FIRST_EXCEPTION return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to **ALL_COMPLETED**.

ALL_COMPLETED return when all futures finish or are cancelled.

concurrent.futures.as_completed(*fs*, *timeout=None*)

Returns an iterator over the **Future** instances (possibly created by different **Executor** instances) given by *fs* that yields futures as they complete (finished or cancelled futures). Any futures given by *fs* that are duplicated will be returned once. Any futures that completed before **as_completed()** is called will be yielded first. The returned iterator raises a **TimeoutError** if **__next__()** is called and the result isn't available after *timeout* seconds from the original call to **as_completed()**. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

PEP 3148 **[https://peps.python.org/pep-3148/]** **– futures - execute computations asynchronously**

The proposal which described this feature for inclusion in the Python standard library.

Exception classes

exception concurrent.futures.CancelledError

Raised when a future is cancelled.

exception concurrent.futures.TimeoutError

A deprecated alias of **TimeoutError**, raised when a future operation exceeds the given timeout.

Changed in version 3.11: This class was made an alias of **TimeoutError**.

exception concurrent.futures.BrokenExecutor

Derived from **RuntimeError**, this exception class is raised when an executor is broken for some reason, and cannot be used to submit or execute new tasks.

New in version 3.7.

exception concurrent.futures.InvalidStateError

Raised when an operation is performed on a future that is not allowed in the current state.

New in version 3.8.

exception concurrent.futures.thread.BrokenThreadPool

Derived from **BrokenExecutor**, this exception class is raised when one of the workers of a **ThreadPoolExecutor** has failed initializing.

New in version 3.7.

exception concurrent.futures.process.BrokenProcessPool

Derived from **BrokenExecutor** (formerly **RuntimeError**), this exception class is raised when one of the workers of a **ProcessPoolExecutor** has terminated in a non-clean fashion (for example, if it was killed from the outside).

New in version 3.3.

`subprocess` — Subprocess management

Source code: Lib/subprocess.py [https://github.com/python/cpython/tree/3.11/Lib/subprocess.py]

The `subprocess` module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several older modules and functions:

```
os.system
os.spawn*
```

Information about how the `subprocess` module can be used to replace these modules and functions can be found in the following sections.

See also

PEP 324 [https://peps.python.org/pep-0324/] – PEP proposing the subprocess module

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Using the `subprocess` Module

The recommended approach to invoking subprocesses is to use the `run()` function for all use cases it can handle. For more advanced

use cases, the underlying **Popen** interface can be used directly.

subprocess.run(*args*, *, *stdin=None*, *input=None*, *stdout=None*, *stderr=None*, *capture_output=False*, *shell=False*, *cwd=None*, *timeout=None*, *check=False*, *encoding=None*, *errors=None*, *text=None*, *env=None*, *universal_newlines=None*, **other_popen_kwargs*)

Run the command described by *args*. Wait for command to complete, then return a **CompletedProcess** instance.

The arguments shown above are merely the most common ones, described below in Frequently Used Arguments (hence the use of keyword-only notation in the abbreviated signature). The full function signature is largely the same as that of the **Popen** constructor - most of the arguments to this function are passed through to that interface. (*timeout*, *input*, *check*, and *capture_output* are not.)

If *capture_output* is true, stdout and stderr will be captured. When used, the internal **Popen** object is automatically created with `stdout=PIPE` and `stderr=PIPE`. The *stdout* and *stderr* arguments may not be supplied at the same time as *capture_output*. If you wish to capture and combine both streams into one, use `stdout=PIPE` and `stderr=STDOUT` instead of *capture_output*.

The *timeout* argument is passed to **Popen.communicate()**. If the timeout expires, the child process will be killed and waited for. The **TimeoutExpired** exception will be re-raised after the child process has terminated.

The *input* argument is passed to **Popen.communicate()** and thus to the subprocess's stdin. If used it must be a byte sequence, or a string if *encoding* or *errors* is specified or *text* is true. When used, the internal **Popen** object is automatically created with `stdin=PIPE`, and the *stdin* argument may not be used as well.

If *check* is true, and the process exits with a non-zero exit code, a **CalledProcessError** exception will be raised.

Attributes of that exception hold the arguments, the exit code, and stdout and stderr if they were captured.

If *encoding* or *errors* are specified, or *text* is true, file objects for stdin, stdout and stderr are opened in text mode using the specified *encoding* and *errors* or the **io.TextIOWrapper** default. The *universal_newlines* argument is equivalent to *text* and is provided for backwards compatibility. By default, file objects are opened in binary mode.

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current process' environment. It is passed directly to **Popen**. This mapping can be str to str on any platform or bytes to bytes on POSIX platforms much like **os.environ** or **os.environb**.

Examples:

```
>>> subprocess.run(["ls", "-l"])  # doesn't capture
CompletedProcess(args=['ls', '-l'], returncode=0)

CompletedProcess(args=['ls', '-l', '/dev/null'], re
stdout=b'crw-rw-rw- 1 root root 1, 3 Jan 23 16:23 /
```

New in version 3.5.

Changed in version 3.6: Added *encoding* and *errors* parameters

Changed in version 3.7: Added the *text* parameter, as a more understandable alias of *universal_newlines*. Added the *capture_output* parameter.

class subprocess.CompletedProcess

The return value from **`run()`**, representing a process that has finished.

args

The arguments used to launch the process. This may be a list or a string.

returncode

Exit status of the child process. Typically, an exit status of 0 indicates that it ran successfully.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

stdout

Captured stdout from the child process. A bytes sequence, or a string if **`run()`** was called with an encoding, errors, or text=True. `None` if stdout was not captured.

If you ran the process with `stderr=subprocess.STDOUT`, stdout and stderr will be combined in this attribute, and **`stderr`** will be `None`.

stderr

Captured stderr from the child process. A bytes sequence, or a string if **`run()`** was called with an encoding, errors, or text=True. `None` if stderr was not captured.

check_returncode()

If **`returncode`** is non-zero, raise a **`CalledProcessError`**.

New in version 3.5.

subprocess.DEVNULL

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to **Popen** and indicates that the special file **os.devnull** will be used.

New in version 3.3.

subprocess.PIPE

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to **Popen** and indicates that a pipe to the standard stream should be opened. Most useful with **Popen.communicate()**.

subprocess.STDOUT

Special value that can be used as the *stderr* argument to **Popen** and indicates that standard error should go into the same handle as standard output.

exception subprocess.SubprocessError

Base class for all other exceptions from this module.

New in version 3.3.

exception subprocess.TimeoutExpired

Subclass of **SubprocessError**, raised when a timeout expires while waiting for a child process.

cmd

Command that was used to spawn the child process.

timeout

Timeout in seconds.

output

Output of the child process if it was captured by **run()** or **check_output()**. Otherwise, `None`. This is always **bytes** when any output was captured regardless of the `text=True` setting. It may remain `None` instead of `b''` when no output was observed.

stdout

Alias for output, for symmetry with **stderr**.

stderr

Stderr output of the child process if it was captured by **run()**. Otherwise, None. This is always **bytes** when stderr output was captured regardless of the text=True setting. It may remain None instead of b'' when no stderr output was observed.

New in version 3.3.

Changed in version 3.5: stdout and *stderr* attributes added

exception subprocess.CalledProcessError

Subclass of **SubprocessError**, raised when a process run by **check_call()**, **check_output()**, or **run()** (with check=True) returns a non-zero exit status.

returncode

Exit status of the child process. If the process exited due to a signal, this will be the negative signal number.

cmd

Command that was used to spawn the child process.

output

Output of the child process if it was captured by **run()** or **check_output()**. Otherwise, None.

stdout

Alias for output, for symmetry with **stderr**.

stderr

Stderr output of the child process if it was captured by **run()**. Otherwise, None.

Changed in version 3.5: stdout and *stderr* attributes added

Frequently Used Arguments

To support a wide variety of use cases, the **`Popen`** constructor (and the convenience functions) accept a large number of optional arguments. For most typical use cases, many of these arguments can be safely left at their default values. The arguments that are most commonly needed are:

> *args* is required for all calls and should be a string, or a sequence of program arguments. Providing a sequence of arguments is generally preferred, as it allows the module to take care of any required escaping and quoting of arguments (e.g. to permit spaces in file names). If passing a single string, either *shell* must be **`True`** (see below) or else the string must simply name the program to be executed without specifying any arguments.
>
> *stdin*, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are **`PIPE`**, **`DEVNULL`**, an existing file descriptor (a positive integer), an existing file object with a valid file descriptor, and `None`. **`PIPE`** indicates that a new pipe to the child should be created. **`DEVNULL`** indicates that the special file **`os.devnull`** will be used. With the default settings of `None`, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, *stderr* can be **`STDOUT`**, which indicates that the stderr data from the child process should be captured into the same file handle as for *stdout*.
>
> If *encoding* or *errors* are specified, or *text* (also known as *universal_newlines*) is true, the file objects *stdin*, *stdout* and *stderr* will be opened in text mode using the *encoding* and *errors* specified in the call or

the defaults for **io.TextIOWrapper**.

For *stdin*, line ending characters `'\n'` in the input will be converted to the default line separator **os.linesep**. For *stdout* and *stderr*, all line endings in the output will be converted to `'\n'`. For more information see the documentation of the **io.TextIOWrapper** class when the *newline* argument to its constructor is `None`.

If text mode is not used, *stdin*, *stdout* and *stderr* will be opened as binary streams. No encoding or line ending conversion is performed.

New in version 3.6: Added *encoding* and *errors* parameters.

New in version 3.7: Added the *text* parameter as an alias for *universal_newlines*.

Note

The newlines attribute of the file objects **Popen.stdin**, **Popen.stdout** and **Popen.stderr** are not updated by the **Popen.communicate()** method.

If *shell* is `True`, the specified command will be executed through the shell. This can be useful if you are using Python primarily for the enhanced control flow it offers over most system shells and still want convenient access to other shell features such as shell pipes, filename wildcards, environment variable expansion, and expansion of ~ to a user's home directory. However, note that Python itself offers implementations of many shell-like features (in particular, **glob**, **fnmatch**, **os.walk()**, **os.path.expandvars()**, **os.path.expanduser()**, and **shutil**).

Changed in version 3.3: When *universal_newlines* is `True`, the class uses the encoding **`locale.getpreferredencoding(False)`** instead of `locale.getpreferredencoding()`. See the **`io.TextIOWrapper`** class for more information on this change.

Note

Read the Security Considerations section before using `shell=True`.

These options, along with all of the other options, are described in more detail in the **`Popen`** constructor documentation.

Popen Constructor

The underlying process creation and management in this module is handled by the **`Popen`** class. It offers a lot of flexibility so that developers are able to handle the less common cases not covered by the convenience functions.

class subprocess.Popen(*args*, *bufsize=-1*, *executable=None*, *stdin=None*, *stdout=None*, *stderr=None*, *preexec_fn=None*, *close_fds=True*, *shell=False*, *cwd=None*, *env=None*, *universal_newlines=None*, *startupinfo=None*, *creationflags=0*, *restore_signals=True*, *start_new_session=False*, *pass_fds=()*, ***, *group=None*, *extra_groups=None*, *user=None*, *umask=-1*, *encoding=None*, *errors=None*, *text=None*, *pipesize=-1*, *process_group=None*)

Execute a child program in a new process. On POSIX, the class uses **`os.execvpe()`**-like behavior to execute the child program. On Windows, the class uses the Windows `CreateProcess()` function. The arguments to **`Popen`** are as follows.

args should be a sequence of program arguments or else a single string or path-like object. By default, the program to

execute is the first item in *args* if *args* is a sequence. If *args* is a string, the interpretation is platform-dependent and described below. See the *shell* and *executable* arguments for additional differences from the default behavior. Unless otherwise stated, it is recommended to pass *args* as a sequence.

Warning

For maximum reliability, use a fully qualified path for the executable. To search for an unqualified name on **PATH**, use **shutil.which()**. On all platforms, passing **sys.executable** is the recommended way to launch the current Python interpreter again, and use the `-m` command-line format to launch an installed module.

Resolving the path of *executable* (or the first item of *args*) is platform dependent. For POSIX, see **os.execvpe()**, and note that when resolving or searching for the executable path, *cwd* overrides the current working directory and *env* can override the `PATH` environment variable. For Windows, see the documentation of the `lpApplicationName` and `lpCommandLine` parameters of WinAPI `CreateProcess`, and note that when resolving or searching for the executable path with `shell=False`, *cwd* does not override the current working directory and *env* cannot override the `PATH` environment variable. Using a full path avoids all of these variations.

An example of passing some arguments to an external program as a sequence is:

```
Popen(["/usr/bin/git", "commit", "-m", "Fixes a bug
```

On POSIX, if *args* is a string, the string is interpreted as the name or path of the program to execute. However, this can only be done if not passing arguments to the program.

Note

It may not be obvious how to break a shell command into a sequence of arguments, especially in complex cases.

`shlex.split()` can illustrate how to determine the correct tokenization for *args*:

```
>>> import shlex, subprocess
>>> command_line = input()
/bin/vikings -input eggs.txt -output "spam spam.tx
>>> args = shlex.split(command_line)
>>> print(args)
['/bin/vikings', '-input', 'eggs.txt', '-output',
>>> p = subprocess.Popen(args) # Success!
```

Note in particular that options (such as *-input*) and arguments (such as *eggs.txt*) that are separated by whitespace in the shell go in separate list elements, while arguments that need quoting or backslash escaping when used in the shell (such as filenames containing spaces or the *echo* command shown above) are single list elements.

On Windows, if *args* is a sequence, it will be converted to a string in a manner described in Converting an argument sequence to a string on Windows. This is because the underlying `CreateProcess()` operates on strings.

Changed in version 3.6: args parameter accepts a path-like object if *shell* is `False` and a sequence containing path-like objects on POSIX.

Changed in version 3.8: args parameter accepts a path-like object if *shell* is `False` and a sequence containing bytes and path-like objects on Windows.

The *shell* argument (which defaults to `False`) specifies whether to use the shell as the program to execute. If *shell* is `True`, it is recommended to pass *args* as a string rather than as a sequence.

On POSIX with `shell=True`, the shell defaults to `/bin/sh`. If *args* is a string, the string specifies the command to execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell

prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If *args* is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, **Popen** does the equivalent of:

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

On Windows with `shell=True`, the **COMSPEC** environment variable specifies the default shell. The only time you need to specify `shell=True` on Windows is when the command you wish to execute is built into the shell (e.g. **dir** or **copy**). You do not need `shell=True` to run a batch file or console-based executable.

Note

Read the Security Considerations section before using `shell=True`.

bufsize will be supplied as the corresponding argument to the **open()** function when creating the stdin/stdout/stderr pipe file objects:

- **0** means unbuffered (read and write are one system call and can return short)
- **1** means line buffered (only usable if `universal_newlines=True` i.e., in a text mode)
- any other positive value means use a buffer of approximately that size
- negative bufsize (the default) means the system default of io.DEFAULT_BUFFER_SIZE will be used.

Changed in version 3.3.1: bufsize now defaults to -1 to enable buffering by default to match the behavior that most code expects. In versions prior to Python 3.2.4 and 3.3.1 it incorrectly defaulted to **0** which was unbuffered and allowed short reads. This was unintentional and did not match the behavior of Python 2 as most code expected.

The *executable* argument specifies a replacement program to

execute. It is very seldom needed. When `shell=False`, *executable* replaces the program to execute specified by *args*. However, the original *args* is still passed to the program. Most programs treat the program specified by *args* as the command name, which can then be different from the program actually executed. On POSIX, the *args* name becomes the display name for the executable in utilities such as **ps**. If `shell=True`, on POSIX the *executable* argument specifies a replacement shell for the default `/bin/sh`.

Changed in version 3.6: executable parameter accepts a path-like object on POSIX.

Changed in version 3.8: executable parameter accepts a bytes and path-like object on Windows.

stdin, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are **`PIPE`**, **`DEVNULL`**, an existing file descriptor (a positive integer), an existing file object with a valid file descriptor, and `None`. **`PIPE`** indicates that a new pipe to the child should be created. **`DEVNULL`** indicates that the special file **`os.devnull`** will be used. With the default settings of `None`, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, *stderr* can be **`STDOUT`**, which indicates that the stderr data from the applications should be captured into the same file handle as for stdout.

If *preexec_fn* is set to a callable object, this object will be called in the child process just before the child is executed. (POSIX only)

Warning

The *preexec_fn* parameter is NOT SAFE to use in the presence of threads in your application. The child process could deadlock before exec is called.

Note

If you need to modify the environment for the child use the *env* parameter rather than doing it in a *preexec_fn*. The *start_new_session* and *process_group* parameters should take the place of code using *preexec_fn* to call **os.setsid()** or **os.setpgid()** in the child.

Changed in version 3.8: The *preexec_fn* parameter is no longer supported in subinterpreters. The use of the parameter in a subinterpreter raises **RuntimeError**. The new restriction may affect applications that are deployed in mod_wsgi, uWSGI, and other embedded environments.

If *close_fds* is true, all file descriptors except **0**, **1** and **2** will be closed before the child process is executed. Otherwise when *close_fds* is false, file descriptors obey their inheritable flag as described in Inheritance of File Descriptors.

On Windows, if *close_fds* is true then no handles will be inherited by the child process unless explicitly passed in the `handle_list` element of **STARTUPINFO.lpAttributeList**, or by standard handle redirection.

Changed in version 3.2: The default for *close_fds* was changed from **False** to what is described above.

Changed in version 3.7: On Windows the default for *close_fds* was changed from **False** to **True** when redirecting the standard handles. It's now possible to set *close_fds* to **True** when redirecting the standard handles.

pass_fds is an optional sequence of file descriptors to keep open between the parent and child. Providing any *pass_fds* forces *close_fds* to be **True**. (POSIX only)

Changed in version 3.2: The *pass_fds* parameter was added.

If *cwd* is not `None`, the function changes the working directory to *cwd* before executing the child. *cwd* can be a string, bytes or path-like object. On POSIX, the function looks for *executable* (or for the first item in *args*) relative to *cwd* if

the executable path is a relative path.

Changed in version 3.6: cwd parameter accepts a path-like object on POSIX.

Changed in version 3.7: cwd parameter accepts a path-like object on Windows.

Changed in version 3.8: cwd parameter accepts a bytes object on Windows.

If *restore_signals* is true (the default) all signals that Python has set to SIG_IGN are restored to SIG_DFL in the child process before the exec. Currently this includes the SIGPIPE, SIGXFZ and SIGXFSZ signals. (POSIX only)

Changed in version 3.2: restore_signals was added.

If *start_new_session* is true the `setsid()` system call will be made in the child process prior to the execution of the subprocess.

Availability: POSIX

Changed in version 3.2: start_new_session was added.

If *process_group* is a non-negative integer, the `setpgid(0, value)` system call will be made in the child process prior to the execution of the subprocess.

Availability: POSIX

Changed in version 3.11: process_group was added.

If *group* is not `None`, the setregid() system call will be made in the child process prior to the execution of the subprocess. If the provided value is a string, it will be looked up via **`grp.getgrnam()`** and the value in `gr_gid` will be used. If the value is an integer, it will be passed verbatim. (POSIX only)

Availability: POSIX

New in version 3.9.

If *extra_groups* is not `None`, the setgroups() system call will be made in the child process prior to the execution of the subprocess. Strings provided in *extra_groups* will be looked up via **`grp.getgrnam()`** and the values in `gr_gid` will be used. Integer values will be passed verbatim. (POSIX only)

Availability: POSIX

New in version 3.9.

If *user* is not `None`, the setreuid() system call will be made in the child process prior to the execution of the subprocess. If the provided value is a string, it will be looked up via **`pwd.getpwnam()`** and the value in `pw_uid` will be used. If the value is an integer, it will be passed verbatim. (POSIX only)

Availability: POSIX

New in version 3.9.

If *umask* is not negative, the umask() system call will be made in the child process prior to the execution of the subprocess.

Availability: POSIX

New in version 3.9.

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current process' environment. This mapping can be str to str on any platform or bytes to bytes on POSIX platforms much like **`os.environ`** or **`os.environb`**.

Note

If specified, *env* must provide any variables required for the program to execute. On Windows, in order to run a side-by-side assembly [https://en.wikipedia.org/wiki/Side-by-

Side_Assembly] the specified *env* **must** include a valid **`SystemRoot`**.

If *encoding* or *errors* are specified, or *text* is true, the file objects *stdin*, *stdout* and *stderr* are opened in text mode with the specified *encoding* and *errors*, as described above in Frequently Used Arguments. The *universal_newlines* argument is equivalent to *text* and is provided for backwards compatibility. By default, file objects are opened in binary mode.

New in version 3.6: encoding and *errors* were added.

New in version 3.7: text was added as a more readable alias for *universal_newlines*.

If given, *startupinfo* will be a **`STARTUPINFO`** object, which is passed to the underlying `CreateProcess` function. *creationflags*, if given, can be one or more of the following flags:

- **`CREATE_NEW_CONSOLE`**
- **`CREATE_NEW_PROCESS_GROUP`**
- **`ABOVE_NORMAL_PRIORITY_CLASS`**
- **`BELOW_NORMAL_PRIORITY_CLASS`**
- **`HIGH_PRIORITY_CLASS`**
- **`IDLE_PRIORITY_CLASS`**
- **`NORMAL_PRIORITY_CLASS`**
- **`REALTIME_PRIORITY_CLASS`**
- **`CREATE_NO_WINDOW`**
- **`DETACHED_PROCESS`**
- **`CREATE_DEFAULT_ERROR_MODE`**
- **`CREATE_BREAKAWAY_FROM_JOB`**

pipesize can be used to change the size of the pipe when **`PIPE`** is used for *stdin*, *stdout* or *stderr*. The size of the pipe is only changed on platforms that support this (only Linux at this time of writing). Other platforms will ignore this parameter.

New in version 3.10: The `pipesize` parameter was added.

Popen objects are supported as context managers via the **with** statement: on exit, standard file descriptors are closed, and the process is waited for.

```
with Popen(["ifconfig"], stdout=PIPE) as proc:
    log.write(proc.stdout.read())
```

Popen and the other functions in this module that use it raise an auditing event `subprocess.Popen` with arguments `executable`, `args`, `cwd`, and `env`. The value for `args` may be a single string or a list of strings, depending on platform.

Changed in version 3.2: Added context manager support.

Changed in version 3.6: Popen destructor now emits a **ResourceWarning** warning if the child process is still running.

Changed in version 3.8: Popen can use **os.posix_spawn()** in some cases for better performance. On Windows Subsystem for Linux and QEMU User Emulation, Popen constructor using **os.posix_spawn()** no longer raise an exception on errors like missing program, but the child process fails with a non-zero **returncode**.

Exceptions

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent.

The most common exception raised is **OSError**. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for **OSError** exceptions. Note that, when `shell=True`, **OSError** will be raised by the child only if the selected shell itself was not found. To determine if the shell failed to find the requested application, it is necessary to check the return code or output from the subprocess.

A **ValueError** will be raised if **Popen** is called with invalid arguments.

check_call() and **check_output()** will raise **CalledProcessError** if the called process returns a non-zero return code.

All of the functions and methods that accept a *timeout* parameter, such as **call()** and **Popen.communicate()** will raise **TimeoutExpired** if the timeout expires before the process exits.

Exceptions defined in this module all inherit from **SubprocessError**.

> *New in version 3.3:* The **SubprocessError** base class was added.

Security Considerations

Unlike some other popen functions, this implementation will never implicitly call a system shell. This means that all characters, including shell metacharacters, can safely be passed to child processes. If the shell is invoked explicitly, via `shell=True`, it is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection [https://en.wikipedia.org/wiki/Shell_injection#Shell_injection] vulnerabilities. On some platforms, it is possible to use **shlex.quote()** for this escaping.

Popen Objects

Instances of the **Popen** class have the following methods:

Popen.poll()

> Check if child process has terminated. Set and return **returncode** attribute. Otherwise, returns `None`.

Popen.wait(*timeout=None*)

> Wait for child process to terminate. Set and return

returncode attribute.

If the process does not terminate after *timeout* seconds, raise a **TimeoutExpired** exception. It is safe to catch this exception and retry the wait.

Note

This will deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use **Popen.communicate()** when using pipes to avoid that.

Note

The function is implemented using a busy loop (non-blocking call and short sleeps). Use the **asyncio** module for an asynchronous wait: see **asyncio.create_subprocess_exec**.

Changed in version 3.3: timeout was added.

Popen.communicate(*input=None*, *timeout=None*)

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate and set the **returncode** attribute. The optional *input* argument should be data to be sent to the child process, or `None`, if no data should be sent to the child. If streams were opened in text mode, *input* must be a string. Otherwise, it must be bytes.

communicate() returns a tuple `(stdout_data, stderr_data)`. The data will be strings if streams were opened in text mode; otherwise, bytes.

Note that if you want to send data to the process's stdin, you need to create the Popen object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or

`stderr=PIPE` too.

If the process does not terminate after *timeout* seconds, a **`TimeoutExpired`** exception will be raised. Catching this exception and retrying communication will not lose any output.

The child process is not killed if the timeout expires, so in order to cleanup properly a well-behaved application should kill the child process and finish communication:

```
proc = subprocess.Popen(...)
try:
    outs, errs = proc.communicate(timeout=15)
except TimeoutExpired:
    proc.kill()
    outs, errs = proc.communicate()
```

Note

The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

Changed in version 3.3: timeout was added.

Popen.send_signal(*signal*)

Sends the signal *signal* to the child.

Do nothing if the process completed.

Note

On Windows, SIGTERM is an alias for **`terminate()`**. CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a *creationflags* parameter which includes `CREATE_NEW_PROCESS_GROUP`.

Popen.terminate()

Stop the child. On POSIX OSs the method sends SIGTERM to the child. On Windows the Win32 API function **`TerminateProcess()`** is called to stop the child.

Popen.kill()

Kills the child. On POSIX OSs the function sends SIGKILL to the child. On Windows **`kill()`** is an alias for **`terminate()`**.

The following attributes are also available:

Popen.args

The *args* argument as it was passed to **`Popen`** – a sequence of program arguments or else a single string.

New in version 3.3.

Popen.stdin

If the *stdin* argument was **`PIPE`**, this attribute is a writeable stream object as returned by **`open()`**. If the *encoding* or *errors* arguments were specified or the *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stdin* argument was not **`PIPE`**, this attribute is `None`.

Popen.stdout

If the *stdout* argument was **`PIPE`**, this attribute is a readable stream object as returned by **`open()`**. Reading from the stream provides output from the child process. If the *encoding* or *errors* arguments were specified or the *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stdout* argument was not **`PIPE`**, this attribute is `None`.

Popen.stderr

If the *stderr* argument was **`PIPE`**, this attribute is a readable stream object as returned by **`open()`**. Reading from the stream provides error output from the child process. If the

encoding or *errors* arguments were specified or the *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stderr* argument was not **`PIPE`**, this attribute is `None`.

Warning

Use **`communicate()`** rather than **`.stdin.write`**, **`.stdout.read`** or **`.stderr.read`** to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

Popen.pid

The process ID of the child process.

Note that if you set the *shell* argument to `True`, this is the process ID of the spawned shell.

Popen.returncode

The child return code, set by **`poll()`** and **`wait()`** (and indirectly by **`communicate()`**). A `None` value indicates that the process hasn't terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

Windows Popen Helpers

The **`STARTUPINFO`** class and following constants are only available on Windows.

class subprocess.STARTUPINFO(**, dwFlags=0, hStdInput=None, hStdOutput=None, hStdError=None, wShowWindow=0, lpAttributeList=None*)

Partial support of the Windows STARTUPINFO [https://msdn.microsoft.com/en-us/library/ms686331(v=vs.85).aspx] structure is used for **`Popen`** creation. The following attributes can be set by passing them as keyword-only arguments.

Changed in version 3.7: Keyword-only argument support was added.

dwFlags

A bit field that determines whether certain **STARTUPINFO** attributes are used when the process creates a window.

```
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES |
```

hStdInput

If **dwFlags** specifies **STARTF_USESTDHANDLES**, this attribute is the standard input handle for the process. If **STARTF_USESTDHANDLES** is not specified, the default for standard input is the keyboard buffer.

hStdOutput

If **dwFlags** specifies **STARTF_USESTDHANDLES**, this attribute is the standard output handle for the process. Otherwise, this attribute is ignored and the default for standard output is the console window's buffer.

hStdError

If **dwFlags** specifies **STARTF_USESTDHANDLES**, this attribute is the standard error handle for the process. Otherwise, this attribute is ignored and the default for standard error is the console window's buffer.

wShowWindow

If **dwFlags** specifies **STARTF_USESHOWWINDOW**, this attribute can be any of the values that can be specified in the `nCmdShow` parameter for the ShowWindow [https://msdn.microsoft.com/en-us/library/ms633548(v=vs.85).aspx] function, except for `SW_SHOWDEFAULT`. Otherwise, this attribute is ignored.

SW_HIDE is provided for this attribute. It is used when **Popen** is called with `shell=True`.

lpAttributeList

A dictionary of additional attributes for process creation as given in `STARTUPINFOEX`, see UpdateProcThreadAttribute [https://msdn.microsoft.com/en-us/library/windows/desktop/ms686880(v=vs.85).aspx].

Supported attributes:

handle_list

Sequence of handles that will be inherited. *close_fds* must be true if non-empty.

The handles must be temporarily made inheritable by **`os.set_handle_inheritable()`** when passed to the **`Popen`** constructor, else **`OSError`** will be raised with Windows error `ERROR_INVALID_PARAMETER` (87).

Warning

In a multithreaded process, use caution to avoid leaking handles that are marked inheritable when combining this feature with concurrent calls to other process creation functions that inherit all handles such as **`os.system()`**. This also applies to standard handle redirection, which temporarily creates inheritable handles.

New in version 3.7.

Windows Constants

The **`subprocess`** module exposes the following constants.

subprocess.STD_INPUT_HANDLE

The standard input device. Initially, this is the console input

buffer, `CONIN$`.

subprocess.STD_OUTPUT_HANDLE

The standard output device. Initially, this is the active console screen buffer, `CONOUT$`.

subprocess.STD_ERROR_HANDLE

The standard error device. Initially, this is the active console screen buffer, `CONOUT$`.

subprocess.SW_HIDE

Hides the window. Another window will be activated.

subprocess.STARTF_USESTDHANDLES

Specifies that the **`STARTUPINFO.hStdInput`**, **`STARTUPINFO.hStdOutput`**, and **`STARTUPINFO.hStdError`** attributes contain additional information.

subprocess.STARTF_USESHOWWINDOW

Specifies that the **`STARTUPINFO.wShowWindow`** attribute contains additional information.

subprocess.CREATE_NEW_CONSOLE

The new process has a new console, instead of inheriting its parent's console (the default).

subprocess.CREATE_NEW_PROCESS_GROUP

A **`Popen`** `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using **`os.kill()`** on the subprocess.

This flag is ignored if **`CREATE_NEW_CONSOLE`** is specified.

subprocess.ABOVE_NORMAL_PRIORITY_CLASS

A **`Popen`** `creationflags` parameter to specify that a new process will have an above average priority.

New in version 3.7.

subprocess.BELOW_NORMAL_PRIORITY_CLASS

A **Popen** `creationflags` parameter to specify that a new process will have a below average priority.

New in version 3.7.

subprocess.HIGH_PRIORITY_CLASS

A **Popen** `creationflags` parameter to specify that a new process will have a high priority.

New in version 3.7.

subprocess.IDLE_PRIORITY_CLASS

A **Popen** `creationflags` parameter to specify that a new process will have an idle (lowest) priority.

New in version 3.7.

subprocess.NORMAL_PRIORITY_CLASS

A **Popen** `creationflags` parameter to specify that a new process will have an normal priority. (default)

New in version 3.7.

subprocess.REALTIME_PRIORITY_CLASS

A **Popen** `creationflags` parameter to specify that a new process will have realtime priority. You should almost never use REALTIME_PRIORITY_CLASS, because this interrupts system threads that manage mouse input, keyboard input, and background disk flushing. This class can be appropriate for applications that “talk” directly to hardware or that perform brief tasks that should have limited interruptions.

New in version 3.7.

subprocess.CREATE_NO_WINDOW

A **Popen** `creationflags` parameter to specify that a new

process will not create a window.

New in version 3.7.

subprocess.DETACHED_PROCESS

A **Popen** `creationflags` parameter to specify that a new process will not inherit its parent's console. This value cannot be used with CREATE_NEW_CONSOLE.

New in version 3.7.

subprocess.CREATE_DEFAULT_ERROR_MODE

A **Popen** `creationflags` parameter to specify that a new process does not inherit the error mode of the calling process. Instead, the new process gets the default error mode. This feature is particularly useful for multithreaded shell applications that run with hard errors disabled.

New in version 3.7.

subprocess.CREATE_BREAKAWAY_FROM_JOB

A **Popen** `creationflags` parameter to specify that a new process is not associated with the job.

New in version 3.7.

Older high-level API

Prior to Python 3.5, these three functions comprised the high level API to subprocess. You can now use **run()** in many cases, but lots of existing code calls these functions.

subprocess.call(*args*, *, *stdin=None*, *stdout=None*, *stderr=None*, *shell=False*, *cwd=None*, *timeout=None*, ***other_popen_kwargs*)

Run the command described by *args*. Wait for command to complete, then return the **returncode** attribute.

Code needing to capture stdout or stderr should use **run()** instead:

```
run(...).returncode
```

To suppress stdout or stderr, supply a value of **DEVNULL**.

The arguments shown above are merely some common ones. The full function signature is the same as that of the **Popen** constructor - this function passes all supplied arguments other than *timeout* directly through to that interface.

Note

Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

Changed in version 3.3: timeout was added.

subprocess.check_call(*args*, *, *stdin=None*, *stdout=None*, *stderr=None*, *shell=False*, *cwd=None*, *timeout=None*, ***other_popen_kwargs*)

Run command with arguments. Wait for command to complete. If the return code was zero then return, otherwise raise **CalledProcessError**. The **CalledProcessError** object will have the return code in the **returncode** attribute. If **check_call()** was unable to start the process it will propagate the exception that was raised.

Code needing to capture stdout or stderr should use **run()** instead:

```
run(..., check=True)
```

To suppress stdout or stderr, supply a value of **DEVNULL**.

The arguments shown above are merely some common ones. The full function signature is the same as that of the **Popen** constructor - this function passes all supplied arguments other than *timeout* directly through to that interface.

Note

Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

Changed in version 3.3: timeout was added.

subprocess.check_output(*args*, *, *stdin=None*, *stderr=None*, *shell=False*, *cwd=None*, *encoding=None*, *errors=None*, *universal_newlines=None*, *timeout=None*, *text=None*, ***other_popen_kwargs*)

Run command with arguments and return its output.

If the return code was non-zero it raises a **`CalledProcessError`**. The **`CalledProcessError`** object will have the return code in the **`returncode`** attribute and any output in the **`output`** attribute.

This is equivalent to:

```
run(..., check=True, stdout=PIPE).stdout
```

The arguments shown above are merely some common ones. The full function signature is largely the same as that of **`run()`** - most arguments are passed directly through to that interface. One API deviation from **`run()`** behavior exists: passing `input=None` will behave the same as `input=b''` (or `input=''`, depending on other arguments) rather than using the parent's standard input file handle.

By default, this function will return the data as encoded bytes. The actual encoding of the output data may depend on the command being invoked, so the decoding to text will often need to be handled at the application level.

This behaviour may be overridden by setting *text*, *encoding*, *errors*, or *universal_newlines* to `True` as described in Frequently Used Arguments and **`run()`**.

To also capture standard error in the result, use `stderr=subprocess.STDOUT`:

```
>>> subprocess.check_output(
...     "ls non_existent_file; exit 0",
...     stderr=subprocess.STDOUT,
...     shell=True)
'ls: non_existent_file: No such file or directory\n
```

New in version 3.1.

Changed in version 3.3: timeout was added.

Changed in version 3.4: Support for the *input* keyword argument was added.

Changed in version 3.6: encoding and *errors* were added. See **`run()`** for details.

New in version 3.7: text was added as a more readable alias for *universal_newlines*.

Replacing Older Functions with the **`subprocess`** Module

In this section, “a becomes b” means that b can be used as a replacement for a.

Note

All “a” functions in this section fail (more or less) silently if the executed program cannot be found; the “b” replacements raise **`OSError`** instead.

In addition, the replacements using **`check_output()`** will fail with a **`CalledProcessError`** if the requested operation produces a non-zero return code. The output is still available as the **`output`** attribute of the raised exception.

In the following examples, we assume that the relevant functions have already been imported from the `subprocess` module.

Replacing /bin/sh shell command substitution

```
output=$(mycmd myarg)
```

becomes:

```
output = check_output(["mycmd", "myarg"])
```

Replacing shell pipeline

```
output=$(dmesg | grep hda)
```

becomes:

```
p1 = Popen(["dmesg"], stdout=PIPE)
p2 = Popen(["grep", "hda"], stdin=p1.stdout, stdout=PIPE
p1.stdout.close()  # Allow p1 to receive a SIGPIPE if p2
output = p2.communicate()[0]
```

The `p1.stdout.close()` call after starting the p2 is important in order for p1 to receive a SIGPIPE if p2 exits before p1.

Alternatively, for trusted input, the shell's own pipeline support may still be used directly:

```
output=$(dmesg | grep hda)
```

becomes:

```
output = check_output("dmesg | grep hda", shell=True)
```

Replacing `os.system()`

```
sts = os.system("mycmd" + " myarg")
# becomes
retcode = call("mycmd" + " myarg", shell=True)
```

Notes:

- Calling the program through the shell is usually not required.
- The `call()` return value is encoded differently to that of `os.system()`.
- The `os.system()` function ignores SIGINT and SIGQUIT signals while the command is running, but the caller must do this separately when using the `subprocess` module.

A more realistic example would look like this:

```
try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print("Child was terminated by signal", -retcode
    else:
        print("Child returned", retcode, file=sys.stderr
except OSError as e:
    print("Execution failed:", e, file=sys.stderr)
```

Replacing the `os.spawn` family

P_NOWAIT example:

```
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "my
==>
pid = Popen(["/bin/mycmd", "myarg"]).pid
```

P_WAIT example:

```
retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "
==>
retcode = call(["/bin/mycmd", "myarg"])
```

Vector example:

```
os.spawnvp(os.P_NOWAIT, path, args)
==>
Popen([path] + args[1:])
```

Environment example:

```
os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg",
```

```
==>
Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})
```

Replacing `os.popen()`, `os.popen2()`, `os.popen3()`

```
(child_stdin, child_stdout) = os.popen2(cmd, mode, bufsi
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdin, child_stdout) = (p.stdin, p.stdout)

(child_stdin,
 child_stdout,
 child_stderr) = os.popen3(cmd, mode, bufsize)
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fd
(child_stdin,
 child_stdout,
 child_stderr) = (p.stdin, p.stdout, p.stderr)

(child_stdin, child_stdout_and_stderr) = os.popen4(cmd,
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=STDOUT, close_
(child_stdin, child_stdout_and_stderr) = (p.stdin, p.sto
```

Return code handling translates as follows:

```
pipe = os.popen(cmd, 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print("There were some errors")
==>
process = Popen(cmd, stdin=PIPE)
...
process.stdin.close()
```

```
if process.wait() != 0:
    print("There were some errors")
```

Replacing functions from the `popen2` module

Note

If the cmd argument to popen2 functions is a string, the command is executed through /bin/sh. If it is a list, the command is directly executed.

```
(child_stdout, child_stdin) = popen2.popen2("somestring"
==>
p = Popen("somestring", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)

(child_stdout, child_stdin) = popen2.popen2(["mycmd", "m
==>
p = Popen(["mycmd", "myarg"], bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

`popen2.Popen3` and **`popen2.Popen4`** basically work as **`subprocess.Popen`**, except that:

- **`Popen`** raises an exception if the execution fails.
- The *capturestderr* argument is replaced with the *stderr* argument.
- `stdin=PIPE` and `stdout=PIPE` must be specified.
- popen2 closes all file descriptors by default, but you have to specify `close_fds=True` with **`Popen`** to guarantee this behavior on all platforms or past Python versions.

Legacy Shell Invocation Functions

This module also provides the following legacy functions from the 2.x `commands` module. These operations implicitly invoke the system shell and none of the guarantees described above regarding

security and exception handling consistency are valid for these functions.

subprocess.getstatusoutput(*cmd*, *, *encoding*=*None*, *errors*=*None*)

Return `(exitcode, output)` of executing *cmd* in a shell.

Execute the string *cmd* in a shell with **`Popen.check_output()`** and return a 2-tuple `(exitcode, output)`. *encoding* and *errors* are used to decode output; see the notes on Frequently Used Arguments for more details.

A trailing newline is stripped from the output. The exit code for the command can be interpreted as the return code of subprocess. Example:

```
>>> subprocess.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> subprocess.getstatusoutput('cat /bin/junk')
(1, 'cat: /bin/junk: No such file or directory')
>>> subprocess.getstatusoutput('/bin/junk')
(127, 'sh: /bin/junk: not found')
>>> subprocess.getstatusoutput('/bin/kill $$')
(-15, '')
```

Availability: Unix, Windows.

Changed in version 3.3.4: Windows support was added.

The function now returns (exitcode, output) instead of (status, output) as it did in Python 3.3.3 and earlier. exitcode has the same value as **`returncode`**.

New in version 3.11: Added *encoding* and *errors* arguments.

subprocess.getoutput(*cmd*, *, *encoding*=*None*, *errors*=*None*)

Return output (stdout and stderr) of executing *cmd* in a shell.

Like **`getstatusoutput()`**, except the exit code is ignored and the return value is a string containing the command's

output. Example:

```
>>> subprocess.getoutput('ls /bin/ls')
'/bin/ls'
```

Availability: Unix, Windows.

Changed in version 3.3.4: Windows support added

New in version 3.11: Added *encoding* and *errors* arguments.

Notes

Converting an argument sequence to a string on Windows

On Windows, an *args* sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.

See also

shlex
: Module which provides function to parse and escape command lines.

Disabling use of `vfork()` or `posix_spawn()`

On Linux, **`subprocess`** defaults to using the `vfork()` system call internally when it is safe to do so rather than `fork()`. This greatly improves performance.

If you ever encounter a presumed highly unusual situation where you need to prevent `vfork()` from being used by Python, you can set the **`subprocess._USE_VFORK`** attribute to a false value.

```
subprocess._USE_VFORK = False # See CPython
issue gh-NNNNNN.
```

Setting this has no impact on use of `posix_spawn()` which could use `vfork()` internally within its libc implementation. There is a similar **`subprocess._USE_POSIX_SPAWN`** attribute if you need to prevent use of that.

```
subprocess._USE_POSIX_SPAWN = False # See
CPython issue gh-NNNNNN.
```

It is safe to set these to false on any Python version. They will have no effect on older versions when unsupported. Do not assume the attributes are available to read. Despite their names, a true value does not indicate that the corresponding function will be used, only that that it may be.

Please file issues any time you have to use these private knobs with a way to reproduce the issue you were seeing. Link to that issue from a comment in your code.

New in version 3.8: `_USE_POSIX_SPAWN`

New in version 3.11: `_USE_VFORK`

`sched` — Event scheduler

Source code: Lib/sched.py [https://github.com/python/cpython/tree/3.11/Lib/sched.py]

The `sched` module defines a class which implements a general purpose event scheduler:

class sched.scheduler(*timefunc* = *time.monotonic*, *delayfunc* = *time.sleep*)

The `scheduler` class defines a generic interface to scheduling events. It needs two functions to actually deal with the "outside world" — *timefunc* should be callable without arguments, and return a number (the "time", in any units whatsoever). The *delayfunc* function should be callable with one argument, compatible with the output of *timefunc*, and should delay that many time units. *delayfunc* will also be called with the argument `0` after each event is run to allow other threads an opportunity to run in multi-threaded applications.

Changed in version 3.3: *timefunc* and *delayfunc* parameters are optional.

Changed in version 3.3: `scheduler` class can be safely used in multi-threaded environments.

Example:

```
>>> import sched, time
>>> s = sched.scheduler(time.time, time.sleep)
>>> def print_time(a='default'):
...     print("From print_time", time.time(), a)
...
>>> def print_some_times():
```

```
...     print(time.time())
...     s.enter(10, 1, print_time)
...     s.enter(5, 2, print_time, argument=('positional'
...     s.enter(5, 1, print_time, kwargs={'a': 'keyword'
...     s.run()
...     print(time.time())
...
>>> print_some_times()
930343690.257
From print_time 930343695.274 positional
From print_time 930343695.275 keyword
From print_time 930343700.273 default
930343700.276
```

Scheduler Objects

`scheduler` instances have the following methods and attributes:

scheduler.enterabs(*time*, *priority*, *action*, *argument=()*, *kwargs={}*)

Schedule a new event. The *time* argument should be a numeric type compatible with the return value of the *timefunc* function passed to the constructor. Events scheduled for the same *time* will be executed in the order of their *priority*. A lower number represents a higher priority.

Executing the event means executing `action(*argument, **kwargs)`. *argument* is a sequence holding the positional arguments for *action*. *kwargs* is a dictionary holding the keyword arguments for *action*.

Return value is an event which may be used for later cancellation of the event (see **`cancel()`**).

Changed in version 3.3: argument parameter is optional.

Changed in version 3.3: kwargs parameter was added.

scheduler.enter(*delay*, *priority*, *action*, *argument=()*, *kwargs={}*)

Schedule an event for *delay* more time units. Other than the

relative time, the other arguments, the effect and the return value are the same as those for **`enterabs()`**.

Changed in version 3.3: argument parameter is optional.

Changed in version 3.3: kwargs parameter was added.

scheduler.cancel(*event*)

Remove the event from the queue. If *event* is not an event currently in the queue, this method will raise a **`ValueError`**.

scheduler.empty()

Return `True` if the event queue is empty.

scheduler.run(*blocking=True*)

Run all scheduled events. This method will wait (using the **`delayfunc()`** function passed to the constructor) for the next event, then execute it and so on until there are no more scheduled events.

If *blocking* is false executes the scheduled events due to expire soonest (if any) and then return the deadline of the next scheduled call in the scheduler (if any).

Either *action* or *delayfunc* can raise an exception. In either case, the scheduler will maintain a consistent state and propagate the exception. If an exception is raised by *action*, the event will not be attempted in future calls to **`run()`**.

If a sequence of events takes longer to run than the time available before the next event, the scheduler will simply fall behind. No events will be dropped; the calling code is responsible for canceling events which are no longer pertinent.

Changed in version 3.3: blocking parameter was added.

scheduler.queue

Read-only attribute returning a list of upcoming events in the order they will be run. Each event is shown as a named tuple with the following fields: time, priority, action, argument, kwargs.

`queue` — A synchronized queue class

Source code: Lib/queue.py [https://github.com/python/cpython/tree/3.11/Lib/queue.py]

The `queue` module implements multi-producer, multi-consumer queues. It is especially useful in threaded programming when information must be exchanged safely between multiple threads. The `Queue` class in this module implements all the required locking semantics.

The module implements three types of queue, which differ only in the order in which the entries are retrieved. In a FIFO queue, the first tasks added are the first retrieved. In a LIFO queue, the most recently added entry is the first retrieved (operating like a stack). With a priority queue, the entries are kept sorted (using the `heapq` module) and the lowest valued entry is retrieved first.

Internally, those three types of queues use locks to temporarily block competing threads; however, they are not designed to handle reentrancy within a thread.

In addition, the module implements a “simple” FIFO queue type, `SimpleQueue`, whose specific implementation provides additional guarantees in exchange for the smaller functionality.

The `queue` module defines the following classes and exceptions:

class queue.Queue(*maxsize=0*)

Constructor for a FIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

class queue.LifoQueue(*maxsize=0*)

Constructor for a LIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

class queue.PriorityQueue(*maxsize=0*)

Constructor for a priority queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

The lowest valued entries are retrieved first (the lowest valued entry is the one returned by `sorted(list(entries))[0]`). A typical pattern for entries is a tuple in the form: `(priority_number, data)`.

If the *data* elements are not comparable, the data can be wrapped in a class that ignores the data item and only compares the priority number:

```
from dataclasses import dataclass, field
from typing import Any

@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)
```

class queue.SimpleQueue

Constructor for an unbounded FIFO queue. Simple queues lack advanced functionality such as task tracking.

New in version 3.7.

exception queue.Empty

Exception raised when non-blocking **`get()`** (or

get_nowait()) is called on a **Queue** object which is empty.

exception queue.Full

Exception raised when non-blocking **put()** (or **put_nowait()**) is called on a **Queue** object which is full.

Queue Objects

Queue objects (**Queue**, **LifoQueue**, or **PriorityQueue**) provide the public methods described below.

Queue.qsize()

Return the approximate size of the queue. Note, qsize() > 0 doesn't guarantee that a subsequent get() will not block, nor will qsize() < maxsize guarantee that put() will not block.

Queue.empty()

Return `True` if the queue is empty, `False` otherwise. If empty() returns `True` it doesn't guarantee that a subsequent call to put() will not block. Similarly, if empty() returns `False` it doesn't guarantee that a subsequent call to get() will not block.

Queue.full()

Return `True` if the queue is full, `False` otherwise. If full() returns `True` it doesn't guarantee that a subsequent call to get() will not block. Similarly, if full() returns `False` it doesn't guarantee that a subsequent call to put() will not block.

Queue.put(*item*, *block*=*True*, *timeout*=*None*)

Put *item* into the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until a free slot is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the **Full** exception if no free slot was available within that time. Otherwise (*block* is false), put an item on the queue if a free slot is immediately

available, else raise the **`Full`** exception (*timeout* is ignored in that case).

Queue.put_nowait(*item*)

Equivalent to `put(item, block=False)`.

Queue.get(*block*=*True*, *timeout*=*None*)

Remove and return an item from the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the **`Empty`** exception if no item was available within that time. Otherwise (*block* is false), return an item if one is immediately available, else raise the **`Empty`** exception (*timeout* is ignored in that case).

Prior to 3.0 on POSIX systems, and for all versions on Windows, if *block* is true and *timeout* is `None`, this operation goes into an uninterruptible wait on an underlying lock. This means that no exceptions can occur, and in particular a SIGINT will not trigger a **`KeyboardInterrupt`**.

Queue.get_nowait()

Equivalent to `get(False)`.

Two methods are offered to support tracking whether enqueued tasks have been fully processed by daemon consumer threads.

Queue.task_done()

Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each **`get()`** used to fetch a task, a subsequent call to **`task_done()`** tells the queue that the processing on the task is complete.

If a **`join()`** is currently blocking, it will resume when all items have been processed (meaning that a **`task_done()`** call was received for every item that had been **`put()`** into the queue).

Raises a **`ValueError`** if called more times than there were items placed in the queue.

Queue.join()

Blocks until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls **`task_done()`** to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, **`join()`** unblocks.

Example of how to wait for enqueued tasks to be completed:

```
import threading
import queue

q = queue.Queue()

def worker():
    while True:
        item = q.get()
        print(f'Working on {item}')
        print(f'Finished {item}')
        q.task_done()

# Turn-on the worker thread.
threading.Thread(target=worker, daemon=True).start()

# Send thirty task requests to the worker.
for item in range(30):
    q.put(item)

# Block until all tasks are done.
q.join()
print('All work completed')
```

SimpleQueue Objects

SimpleQueue objects provide the public methods described below.

SimpleQueue.qsize()

Return the approximate size of the queue. Note, qsize() > 0 doesn't guarantee that a subsequent get() will not block.

SimpleQueue.empty()

Return `True` if the queue is empty, `False` otherwise. If empty() returns `False` it doesn't guarantee that a subsequent call to get() will not block.

SimpleQueue.put(*item*, *block*=*True*, *timeout*=*None*)

Put *item* into the queue. The method never blocks and always succeeds (except for potential low-level errors such as failure to allocate memory). The optional args *block* and *timeout* are ignored and only provided for compatibility with **Queue.put()**.

CPython implementation detail: This method has a C implementation which is reentrant. That is, a `put()` or `get()` call can be interrupted by another `put()` call in the same thread without deadlocking or corrupting internal state inside the queue. This makes it appropriate for use in destructors such as `__del__` methods or **weakref** callbacks.

SimpleQueue.put_nowait(*item*)

Equivalent to `put(item, block=False)`, provided for compatibility with **Queue.put_nowait()**.

SimpleQueue.get(*block*=*True*, *timeout*=*None*)

Remove and return an item from the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the

Empty exception if no item was available within that time. Otherwise (*block* is false), return an item if one is immediately available, else raise the **Empty** exception (*timeout* is ignored in that case).

SimpleQueue.get_nowait()

Equivalent to `get(False)`.

See also

Class **multiprocessing.Queue**

A queue class for use in a multi-processing (rather than multi-threading) context.

collections.deque is an alternative implementation of unbounded queues with fast atomic **append()** and **popleft()** operations that do not require locking and also support indexing.

`contextvars` — Context Variables

This module provides APIs to manage, store, and access context-local state. The `ContextVar` class is used to declare and work with *Context Variables*. The `copy_context()` function and the `Context` class should be used to manage the current context in asynchronous frameworks.

Context managers that have state should use Context Variables instead of `threading.local()` to prevent their state from bleeding to other code unexpectedly, when used in concurrent code.

See also **PEP 567** [https://peps.python.org/pep-0567/] for additional details.

New in version 3.7.

Context Variables

class contextvars.ContextVar(*name*[, *, *default*])

This class is used to declare a new Context Variable, e.g.:

```
var: ContextVar[int] = ContextVar('var', default=42
```

The required *name* parameter is used for introspection and debug purposes.

The optional keyword-only *default* parameter is returned by `ContextVar.get()` when no value for the variable is found in the current context.

Important: Context Variables should be created at the top module level and never in closures. `Context` objects hold

strong references to context variables which prevents context variables from being properly garbage collected.

name

The name of the variable. This is a read-only property.

New in version 3.7.1.

get([*default*])

Return a value for the context variable for the current context.

If there is no value for the variable in the current context, the method will:

- return the value of the *default* argument of the method, if provided; or
- return the default value for the context variable, if it was created with one; or
- raise a **`LookupError`**.

set(*value*)

Call to set a new value for the context variable in the current context.

The required *value* argument is the new value for the context variable.

Returns a **`Token`** object that can be used to restore the variable to its previous value via the **`ContextVar.reset()`** method.

reset(*token*)

Reset the context variable to the value it had before the **`ContextVar.set()`** that created the *token* was used.

For example:

```
var = ContextVar('var')
```

```
token = var.set('new value')
# code that uses 'var'; var.get() returns 'new
var.reset(token)

# After the reset call the var has no value aga
# var.get() would raise a LookupError.
```

class contextvars.Token

Token objects are returned by the **`ContextVar.set()`** method. They can be passed to the **`ContextVar.reset()`** method to revert the value of the variable to what it was before the corresponding *set*.

var

A read-only property. Points to the **`ContextVar`** object that created the token.

old_value

A read-only property. Set to the value the variable had before the **`ContextVar.set()`** method call that created the token. It points to **`Token.MISSING`** if the variable was not set before the call.

MISSING

A marker object used by **`Token.old_value`**.

Manual Context Management

contextvars.copy_context()

Returns a copy of the current **`Context`** object.

The following snippet gets a copy of the current context and prints all variables and their values that are set in it:

```
ctx: Context = copy_context()
print(list(ctx.items()))
```

The function has an O(1) complexity, i.e. works equally fast for contexts with a few context variables and for contexts that have a lot of them.

class contextvars.Context

A mapping of **`ContextVars`** to their values.

`Context()` creates an empty context with no values in it. To get a copy of the current context use the **`copy_context()`** function.

Context implements the **`collections.abc.Mapping`** interface.

run(*callable*, **args*, ***kwargs*)

Execute `callable(*args, **kwargs)` code in the context object the *run* method is called on. Return the result of the execution or propagate an exception if one occurred.

Any changes to any context variables that *callable* makes will be contained in the context object:

```
var = ContextVar('var')
var.set('spam')

def main():
    # 'var' was set to 'spam' before
    # calling 'copy_context()' and 'ctx.run(mai
    # var.get() == ctx[var] == 'spam'

    var.set('ham')

    # Now, after setting 'var' to 'ham':
    # var.get() == ctx[var] == 'ham'

ctx = copy_context()

# Any changes that the 'main' function makes to
```

```
# will be contained in 'ctx'.
ctx.run(main)

# The 'main()' function was run in the 'ctx' co
# so changes to 'var' are contained in it:
# ctx[var] == 'ham'

# However, outside of 'ctx', 'var' is still set
# var.get() == 'spam'
```

The method raises a **RuntimeError** when called on the same context object from more than one OS thread, or when called recursively.

copy()

Return a shallow copy of the context object.

var in context

Return `True` if the *context* has a value for *var* set; return `False` otherwise.

context[var]

Return the value of the *var* **ContextVar** variable. If the variable is not set in the context object, a **KeyError** is raised.

get(*var*[, *default*])

Return the value for *var* if *var* has the value in the context object. Return *default* otherwise. If *default* is not given, return `None`.

iter(context)

Return an iterator over the variables stored in the context object.

len(proxy)

Return the number of variables set in the context

object.

keys()
: Return a list of all variables in the context object.

values()
: Return a list of all variables' values in the context object.

items()
: Return a list of 2-tuples containing all variables and their values in the context object.

asyncio support

Context variables are natively supported in **asyncio** and are ready to be used without any extra configuration. For example, here is a simple echo server, that uses a context variable to make the address of a remote client available in the Task that handles that client:

```
import asyncio
import contextvars

client_addr_var = contextvars.ContextVar('client_addr')

def render_goodbye():
    # The address of the currently handled client can be
    # without passing it explicitly to this function.

    client_addr = client_addr_var.get()
    return f'Good bye, client @ {client_addr}\n'.encode(

async def handle_request(reader, writer):
    addr = writer.transport.get_extra_info('socket').get
    client_addr_var.set(addr)

    # In any code that we call is now possible to get
```

```
    # client's address by calling 'client_addr_var.get()

    while True:
        line = await reader.readline()
        print(line)
        if not line.strip():
            break
        writer.write(line)

    writer.write(render_goodbye())
    writer.close()

async def main():
    srv = await asyncio.start_server(
        handle_request, '127.0.0.1', 8081)

    async with srv:
        await srv.serve_forever()

asyncio.run(main())

# To test it you can use telnet:
#     telnet 127.0.0.1 8081
```

`_thread` — Low-level threading API

This module provides low-level primitives for working with multiple threads (also called *light-weight processes* or *tasks*) — multiple threads of control sharing their global data space. For synchronization, simple locks (also called *mutexes* or *binary semaphores*) are provided. The `threading` module provides an easier to use and higher-level threading API built on top of this module.

Changed in version 3.7: This module used to be optional, it is now always available.

This module defines the following constants and functions:

exception _thread.error

Raised on thread-specific errors.

Changed in version 3.3: This is now a synonym of the built-in `RuntimeError`.

_thread.LockType

This is the type of lock objects.

_thread.start_new_thread(*function*, *args*[, *kwargs*])

Start a new thread and return its identifier. The thread executes the function *function* with the argument list *args* (which must be a tuple). The optional *kwargs* argument specifies a dictionary of keyword arguments.

When the function returns, the thread silently exits.

When the function terminates with an unhandled exception,

`sys.unraisablehook()` is called to handle the exception. The *object* attribute of the hook argument is *function*. By default, a stack trace is printed and then the thread exits (but other threads continue to run).

When the function raises a `SystemExit` exception, it is silently ignored.

Changed in version 3.8: `sys.unraisablehook()` is now used to handle unhandled exceptions.

_thread.interrupt_main(*signum=signal.SIGINT*, */*)

Simulate the effect of a signal arriving in the main thread. A thread can use this function to interrupt the main thread, though there is no guarantee that the interruption will happen immediately.

If given, *signum* is the number of the signal to simulate. If *signum* is not given, `signal.SIGINT` is simulated.

If the given signal isn't handled by Python (it was set to `signal.SIG_DFL` or `signal.SIG_IGN`), this function does nothing.

Changed in version 3.10: The *signum* argument is added to customize the signal number.

Note

This does not emit the corresponding signal but schedules a call to the associated handler (if it exists). If you want to truly emit the signal, use `signal.raise_signal()`.

_thread.exit()

Raise the `SystemExit` exception. When not caught, this will cause the thread to exit silently.

_thread.allocate_lock()

Return a new lock object. Methods of locks are described below. The lock is initially unlocked.

_thread.get_ident()

Return the ‘thread identifier’ of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

_thread.get_native_id()

Return the native integral Thread ID of the current thread assigned by the kernel. This is a non-negative integer. Its value may be used to uniquely identify this particular thread system-wide (until the thread terminates, after which the value may be recycled by the OS).

Availability: Windows, FreeBSD, Linux, macOS, OpenBSD, NetBSD, AIX.

New in version 3.8.

_thread.stack_size([*size*])

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a **RuntimeError** is raised. If the specified stack size is invalid, a **ValueError** is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples

of 4096 for the stack size is the suggested approach in the absence of more specific information).

Availability: Windows, pthreads.

Unix platforms with POSIX threads support.

_thread.TIMEOUT_MAX

The maximum value allowed for the *timeout* parameter of **`Lock.acquire()`**. Specifying a timeout greater than this value will raise an **`OverflowError`**.

New in version 3.2.

Lock objects have the following methods:

lock.acquire(*blocking=True*, *timeout=-1*)

Without any optional argument, this method acquires the lock unconditionally, if necessary waiting until it is released by another thread (only one thread at a time can acquire a lock — that's their reason for existence).

If the *blocking* argument is present, the action depends on its value: if it is False, the lock is only acquired if it can be acquired immediately without waiting, while if it is True, the lock is acquired unconditionally as above.

If the floating-point *timeout* argument is present and positive, it specifies the maximum wait time in seconds before returning. A negative *timeout* argument specifies an unbounded wait. You cannot specify a *timeout* if *blocking* is False.

The return value is `True` if the lock is acquired successfully, `False` if not.

Changed in version 3.2: The *timeout* parameter is new.

Changed in version 3.2: Lock acquires can now be interrupted by signals on POSIX.

lock.release()

Releases the lock. The lock must have been acquired earlier, but not necessarily by the same thread.

lock.locked()

Return the status of the lock: `True` if it has been acquired by some thread, `False` if not.

In addition to these methods, lock objects can also be used via the **`with`** statement, e.g.:

```
import _thread

a_lock = _thread.allocate_lock()

with a_lock:
    print("a_lock is locked while this executes")
```

Caveats:

- Threads interact strangely with interrupts: the **`KeyboardInterrupt`** exception will be received by an arbitrary thread. (When the **`signal`** module is available, interrupts always go to the main thread.)
- Calling **`sys.exit()`** or raising the **`SystemExit`** exception is equivalent to calling **`_thread.exit()`**.
- It is not possible to interrupt the **`acquire()`** method on a lock — the **`KeyboardInterrupt`** exception will happen after the lock has been acquired.
- When the main thread exits, it is system defined whether the other threads survive. On most systems, they are killed without executing **`try`** … **`finally`** clauses or executing object destructors.
- When the main thread exits, it does not do any of its usual cleanup (except that **`try`** … **`finally`** clauses are honored), and the standard I/O files are not flushed.

Networking and Interprocess Communication

The modules described in this chapter provide mechanisms for networking and inter-processes communication.

Some modules only work for two processes that are on the same machine, e.g. **`signal`** and **`mmap`**. Other modules support networking protocols that two or more processes can use to communicate across machines.

The list of modules described in this chapter is:

- **`asyncio`** — Asynchronous I/O
- **`socket`** — Low-level networking interface
- **`ssl`** — TLS/SSL wrapper for socket objects
- **`select`** — Waiting for I/O completion
- **`selectors`** — High-level I/O multiplexing
- **`signal`** — Set handlers for asynchronous events
- **`mmap`** — Memory-mapped file support

`asyncio` — Asynchronous I/O

Hello World!

```
import asyncio

async def main():
    print('Hello ...')
    await asyncio.sleep(1)
    print('... World!')

asyncio.run(main())
```

asyncio is a library to write **concurrent** code using the **async/ await** syntax.

asyncio is used as a foundation for multiple Python asynchronous frameworks that provide high-performance network and web-servers, database connection libraries, distributed task queues, etc.

asyncio is often a perfect fit for IO-bound and high-level **structured** network code.

asyncio provides a set of **high-level** APIs to:

- run Python coroutines concurrently and have full control over their execution;
- perform network IO and IPC;
- control subprocesses;
- distribute tasks via queues;
- synchronize concurrent code;

Additionally, there are **low-level** APIs for *library and framework developers* to:

- create and manage event loops, which provide asynchronous

APIs for **networking**, running **subprocesses**, handling **OS signals**, etc;
- implement efficient protocols using transports;
- bridge callback-based libraries and code with async/await syntax.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Runners

Source code: Lib/asyncio/runners.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/runners.py]

This section outlines high-level asyncio primitives to run asyncio code.

They are built on top of an event loop with the aim to simplify async code usage for common wide-spread scenarios.

- Running an asyncio Program
- Runner context manager
- Handling Keyboard Interruption

Running an asyncio Program

asyncio.run(*coro*, *, *debug*=*None*)

Execute the coroutine *coro* and return the result.

This function runs the passed coroutine, taking care of managing the asyncio event loop, *finalizing asynchronous generators*, and closing the threadpool.

This function cannot be called when another asyncio event loop is running in the same thread.

If *debug* is `True`, the event loop will be run in debug mode. `False` disables debug mode explicitly. `None` is used to respect the global Debug Mode settings.

This function always creates a new event loop and closes it at the end. It should be used as a main entry point for asyncio programs, and should ideally only be called once.

Example:

```
async def main():
    await asyncio.sleep(1)
    print('hello')

asyncio.run(main())
```

New in version 3.7.

Changed in version 3.9: Updated to use **`loop.shutdown_default_executor()`**.

Changed in version 3.10: debug is `None` by default to respect the global debug mode settings.

Runner context manager

class asyncio.Runner(*, *debug*=*None*, *loop_factory*=*None*)

A context manager that simplifies *multiple* async function calls in the same context.

Sometimes several top-level async functions should be called in the same event loop and **`contextvars.Context`**.

If *debug* is `True`, the event loop will be run in debug mode. `False` disables debug mode explicitly. `None` is used to respect the global Debug Mode settings.

loop_factory could be used for overriding the loop creation. It is the responsibility of the *loop_factory* to set the created loop as the current one. By default **`asyncio.new_event_loop()`** is used and set as current event loop with **`asyncio.set_event_loop()`** if *loop_factory* is `None`.

Basically, **`asyncio.run()`** example can be rewritten with the runner usage:

```
async def main():
    await asyncio.sleep(1)
    print('hello')
```

```
with asyncio.Runner() as runner:
    runner.run(main())
```

New in version 3.11.

run(*coro*, *, *context=None*)

Run a coroutine *coro* in the embedded loop.

Return the coroutine's result or raise its exception.

An optional keyword-only *context* argument allows specifying a custom **contextvars.Context** for the *coro* to run in. The runner's default context is used if `None`.

This function cannot be called when another asyncio event loop is running in the same thread.

close()

Close the runner.

Finalize asynchronous generators, shutdown default executor, close the event loop and release embedded **contextvars.Context**.

get_loop()

Return the event loop associated with the runner instance.

Note

Runner uses the lazy initialization strategy, its constructor doesn't initialize underlying low-level structures.

Embedded *loop* and *context* are created at the **with** body entering or the first call of **run()** or **get_loop()**.

Handling Keyboard Interruption

New in version 3.11.

When **signal.SIGINT** is raised by `Ctrl-C`, **KeyboardInterrupt** exception is raised in the main thread by default. However this doesn't work with **asyncio** because it can interrupt asyncio internals and can hang the program from exiting.

To mitigate this issue, **asyncio** handles **signal.SIGINT** as follows:

1. **asyncio.Runner.run()** installs a custom **signal.SIGINT** handler before any user code is executed and removes it when exiting from the function.
2. The **Runner** creates the main task for the passed coroutine for its execution.
3. When **signal.SIGINT** is raised by `Ctrl-C`, the custom signal handler cancels the main task by calling **asyncio.Task.cancel()** which raises **asyncio.CancelledError** inside the main task. This causes the Python stack to unwind, `try/except` and `try/finally` blocks can be used for resource cleanup. After the main task is cancelled, **asyncio.Runner.run()** raises **KeyboardInterrupt**.
4. A user could write a tight loop which cannot be interrupted by **asyncio.Task.cancel()**, in which case the second following `Ctrl-C` immediately raises the **KeyboardInterrupt** without cancelling the main task.

Coroutines and Tasks

This section outlines high-level asyncio APIs to work with coroutines and Tasks.

- Coroutines
- Awaitables
- Creating Tasks
- Task Cancellation
- Task Groups
- Sleeping
- Running Tasks Concurrently
- Shielding From Cancellation
- Timeouts
- Waiting Primitives
- Running in Threads
- Scheduling From Other Threads
- Introspection
- Task Object

Coroutines

Source code: Lib/asyncio/coroutines.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/coroutines.py]

Coroutines declared with the async/await syntax is the preferred way of writing asyncio applications. For example, the following snippet of code prints “hello”, waits 1 second, and then prints “world”:

```
>>> import asyncio

>>> async def main():
...     print('hello')
```

```
...     await asyncio.sleep(1)
...     print('world')

>>> asyncio.run(main())
hello
world
```

Note that simply calling a coroutine will not schedule it to be executed:

```
>>> main()
<coroutine object main at 0x1053bb7c8>
```

To actually run a coroutine, asyncio provides the following mechanisms:

- The **`asyncio.run()`** function to run the top-level entry point "main()" function (see the above example.)

- Awaiting on a coroutine. The following snippet of code will print "hello" after waiting for 1 second, and then print "world" after waiting for *another* 2 seconds:

  ```
  import asyncio
  import time

  async def say_after(delay, what):
      await asyncio.sleep(delay)
      print(what)

  async def main():
      print(f"started at {time.strftime('%X')}")

      await say_after(1, 'hello')
      await say_after(2, 'world')

      print(f"finished at {time.strftime('%X')}")

  asyncio.run(main())
  ```

Expected output:

```
started at 17:13:52
hello
world
finished at 17:13:55
```

- The **`asyncio.create_task()`** function to run coroutines concurrently as asyncio **`Tasks`**.

  Let's modify the above example and run two `say_after` coroutines *concurrently*:

  ```
  async def main():
      task1 = asyncio.create_task(
          say_after(1, 'hello'))

      task2 = asyncio.create_task(
          say_after(2, 'world'))

      print(f"started at {time.strftime('%X')}")

      # Wait until both tasks are completed (should t
      # around 2 seconds.)
      await task1
      await task2

      print(f"finished at {time.strftime('%X')}")
  ```

  Note that expected output now shows that the snippet runs 1 second faster than before:

  ```
  started at 17:14:32
  hello
  world
  finished at 17:14:34
  ```

- The **`asyncio.TaskGroup`** class provides a more modern alternative to **`create_task()`**. Using this API, the last example becomes:

```
async def main():
    async with asyncio.TaskGroup() as tg:
        task1 = tg.create_task(
            say_after(1, 'hello'))

        task2 = tg.create_task(
            say_after(2, 'world'))

        print(f"started at {time.strftime('%X')}")

    # The wait is implicit when the context manager

    print(f"finished at {time.strftime('%X')}")
```

The timing and output should be the same as for the previous version.

New in version 3.11: **asyncio.TaskGroup**.

Awaitables

We say that an object is an **awaitable** object if it can be used in an **await** expression. Many asyncio APIs are designed to accept awaitables.

There are three main types of *awaitable* objects: **coroutines**, **Tasks**, and **Futures**.

Coroutines

Python coroutines are *awaitables* and therefore can be awaited from other coroutines:

```
import asyncio

async def nested():
    return 42
```

```
async def main():
    # Nothing happens if we just call "nested()".
    # A coroutine object is created but not awaited,
    # so it *won't run at all*.
    nested()

    # Let's do it differently now and await it:
    print(await nested())  # will print "42".

asyncio.run(main())
```

Important

In this documentation the term “coroutine” can be used for two closely related concepts:

- a *coroutine function*: an **`async def`** function;
- a *coroutine object*: an object returned by calling a *coroutine function*.

Tasks

Tasks are used to schedule coroutines *concurrently*.

When a coroutine is wrapped into a *Task* with functions like **`asyncio.create_task()`** the coroutine is automatically scheduled to run soon:

```
import asyncio

async def nested():
    return 42

async def main():
    # Schedule nested() to run soon concurrently
    # with "main()".
    task = asyncio.create_task(nested())
```

```
    # "task" can now be used to cancel "nested()", or
    # can simply be awaited to wait until it is complete
    await task

asyncio.run(main())
```

Futures

A **`Future`** is a special **low-level** awaitable object that represents an **eventual result** of an asynchronous operation.

When a Future object is *awaited* it means that the coroutine will wait until the Future is resolved in some other place.

Future objects in asyncio are needed to allow callback-based code to be used with async/await.

Normally **there is no need** to create Future objects at the application level code.

Future objects, sometimes exposed by libraries and some asyncio APIs, can be awaited:

```
async def main():
    await function_that_returns_a_future_object()

    # this is also valid:
    await asyncio.gather(
        function_that_returns_a_future_object(),
        some_python_coroutine()
    )
```

A good example of a low-level function that returns a Future object is **`loop.run_in_executor()`**.

Creating Tasks

Source code: Lib/asyncio/tasks.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/tasks.py]

asyncio.create_task(*coro*, *, *name*=*None*, *context*=*None*)

Wrap the *coro* coroutine into a **Task** and schedule its execution. Return the Task object.

If *name* is not `None`, it is set as the name of the task using **Task.set_name()**.

An optional keyword-only *context* argument allows specifying a custom **contextvars.Context** for the *coro* to run in. The current context copy is created when no *context* is provided.

The task is executed in the loop returned by **get_running_loop()**, **RuntimeError** is raised if there is no running loop in current thread.

Note

asyncio.TaskGroup.create_task() is a newer alternative that allows for convenient waiting for a group of related tasks.

Important

Save a reference to the result of this function, to avoid a task disappearing mid-execution. The event loop only keeps weak references to tasks. A task that isn't referenced elsewhere may get garbage collected at any time, even before it's done. For reliable "fire-and-forget" background tasks, gather them in a collection:

```
background_tasks = set()

for i in range(10):
    task = asyncio.create_task(some_coro(param=i))

    # Add task to the set. This creates a strong r
    background_tasks.add(task)
```

```
        # To prevent keeping references to finished ta
        # make each task remove its own reference from
        # completion:
        task.add_done_callback(background_tasks.discar
```

New in version 3.7.

Changed in version 3.8: Added the *name* parameter.

Changed in version 3.11: Added the *context* parameter.

Task Cancellation

Tasks can easily and safely be cancelled. When a task is cancelled, **asyncio.CancelledError** will be raised in the task at the next opportunity.

It is recommended that coroutines use `try/finally` blocks to robustly perform clean-up logic. In case **asyncio.CancelledError** is explicitly caught, it should generally be propagated when clean-up is complete. Most code can safely ignore **asyncio.CancelledError**.

The asyncio components that enable structured concurrency, like **asyncio.TaskGroup** and **asyncio.timeout()**, are implemented using cancellation internally and might misbehave if a coroutine swallows **asyncio.CancelledError**. Similarly, user code should not call **uncancel**.

Task Groups

Task groups combine a task creation API with a convenient and reliable way to wait for all tasks in the group to finish.

class asyncio.TaskGroup

An asynchronous context manager holding a group of tasks. Tasks can be added to the group using **create_task()**. All tasks are awaited when the context manager exits.

New in version 3.11.

create_task(*coro*, ***, *name=None*, *context=None*)

Create a task in this task group. The signature matches that of **asyncio.create_task()**.

Example:

```
async def main():
    async with asyncio.TaskGroup() as tg:
        task1 = tg.create_task(some_coro(...))
        task2 = tg.create_task(another_coro(...))
    print("Both tasks have completed now.")
```

The `async with` statement will wait for all tasks in the group to finish. While waiting, new tasks may still be added to the group (for example, by passing `tg` into one of the coroutines and calling `tg.create_task()` in that coroutine). Once the last task has finished and the `async with` block is exited, no new tasks may be added to the group.

The first time any of the tasks belonging to the group fails with an exception other than **asyncio.CancelledError**, the remaining tasks in the group are cancelled. No further tasks can then be added to the group. At this point, if the body of the `async with` statement is still active (i.e., **__aexit__()** hasn't been called yet), the task directly containing the `async with` statement is also cancelled. The resulting **asyncio.CancelledError** will interrupt an `await`, but it will not bubble out of the containing `async with` statement.

Once all tasks have finished, if any tasks have failed with an exception other than **asyncio.CancelledError**, those exceptions are combined in an **ExceptionGroup** or **BaseExceptionGroup** (as appropriate; see their documentation) which is then raised.

Two base exceptions are treated specially: If any task fails with **KeyboardInterrupt** or **SystemExit**, the task group still cancels the remaining tasks and waits for them, but then the initial

KeyboardInterrupt or **SystemExit** is re-raised instead of **ExceptionGroup** or **BaseExceptionGroup**.

If the body of the `async with` statement exits with an exception (so **__aexit__()** is called with an exception set), this is treated the same as if one of the tasks failed: the remaining tasks are cancelled and then waited for, and non-cancellation exceptions are grouped into an exception group and raised. The exception passed into **__aexit__()**, unless it is **asyncio.CancelledError**, is also included in the exception group. The same special case is made for **KeyboardInterrupt** and **SystemExit** as in the previous paragraph.

Sleeping

coroutine asyncio.sleep(*delay*, *result=None*)

Block for *delay* seconds.

If *result* is provided, it is returned to the caller when the coroutine completes.

`sleep()` always suspends the current task, allowing other tasks to run.

Setting the delay to 0 provides an optimized path to allow other tasks to run. This can be used by long-running functions to avoid blocking the event loop for the full duration of the function call.

Example of coroutine displaying the current date every second for 5 seconds:

```
import asyncio
import datetime

async def display_date():
    loop = asyncio.get_running_loop()
    end_time = loop.time() + 5.0
    while True:
        print(datetime.datetime.now())
```

```
            if (loop.time() + 1.0) >= end_time:
                break
            await asyncio.sleep(1)

    asyncio.run(display_date())
```

Changed in version 3.10: Removed the *loop* parameter.

Running Tasks Concurrently

awaitable asyncio.gather(**aws*, *return_exceptions=False*)

Run awaitable objects in the *aws* sequence *concurrently*.

If any awaitable in *aws* is a coroutine, it is automatically scheduled as a Task.

If all awaitables are completed successfully, the result is an aggregate list of returned values. The order of result values corresponds to the order of awaitables in *aws*.

If *return_exceptions* is `False` (default), the first raised exception is immediately propagated to the task that awaits on `gather()`. Other awaitables in the *aws* sequence **won't be cancelled** and will continue to run.

If *return_exceptions* is `True`, exceptions are treated the same as successful results, and aggregated in the result list.

If `gather()` is *cancelled*, all submitted awaitables (that have not completed yet) are also *cancelled*.

If any Task or Future from the *aws* sequence is *cancelled*, it is treated as if it raised **`CancelledError`** – the `gather()` call is **not** cancelled in this case. This is to prevent the cancellation of one submitted Task/Future to cause other Tasks/Futures to be cancelled.

Note

A more modern way to create and run tasks concurrently

and wait for their completion is **asyncio.TaskGroup**.

Example:

```
import asyncio

async def factorial(name, number):
    f = 1
    for i in range(2, number + 1):
        print(f"Task {name}: Compute factorial({num
        await asyncio.sleep(1)
        f *= i
    print(f"Task {name}: factorial({number}) = {f}"
    return f

async def main():
    # Schedule three calls *concurrently*:
    L = await asyncio.gather(
        factorial("A", 2),
        factorial("B", 3),
        factorial("C", 4),
    )
    print(L)

asyncio.run(main())

# Expected output:
#
#     Task A: Compute factorial(2), currently i=2..
#     Task B: Compute factorial(3), currently i=2..
#     Task C: Compute factorial(4), currently i=2..
#     Task A: factorial(2) = 2
#     Task B: Compute factorial(3), currently i=3..
#     Task C: Compute factorial(4), currently i=3..
#     Task B: factorial(3) = 6
#     Task C: Compute factorial(4), currently i=4..
#     Task C: factorial(4) = 24
#     [2, 6, 24]
```

Note

If *return_exceptions* is False, cancelling gather() after it has been marked done won't cancel any submitted awaitables. For instance, gather can be marked done after propagating an exception to the caller, therefore, calling `gather.cancel()` after catching an exception (raised by one of the awaitables) from gather won't cancel any other awaitables.

Changed in version 3.7: If the *gather* itself is cancelled, the cancellation is propagated regardless of *return_exceptions*.

Changed in version 3.10: Removed the *loop* parameter.

Deprecated since version 3.10: Deprecation warning is emitted if no positional arguments are provided or not all positional arguments are Future-like objects and there is no running event loop.

Shielding From Cancellation

awaitable asyncio.shield(*aw*)

Protect an awaitable object from being **`cancelled`**.

If *aw* is a coroutine it is automatically scheduled as a Task.

The statement:

```
task = asyncio.create_task(something())
res = await shield(task)
```

is equivalent to:

```
res = await something()
```

except that if the coroutine containing it is cancelled, the Task running in `something()` is not cancelled. From the point of view of `something()`, the cancellation did not happen. Although its caller is still cancelled, so the "await" expression

still raises a **`CancelledError`**.

If `something()` is cancelled by other means (i.e. from within itself) that would also cancel `shield()`.

If it is desired to completely ignore cancellation (not recommended) the `shield()` function should be combined with a try/except clause, as follows:

```
task = asyncio.create_task(something())
try:
    res = await shield(task)
except CancelledError:
    res = None
```

Important

Save a reference to tasks passed to this function, to avoid a task disappearing mid-execution. The event loop only keeps weak references to tasks. A task that isn't referenced elsewhere may get garbage collected at any time, even before it's done.

Changed in version 3.10: Removed the *loop* parameter.

Deprecated since version 3.10: Deprecation warning is emitted if *aw* is not Future-like object and there is no running event loop.

Timeouts

coroutine asyncio.timeout(*delay*)

An asynchronous context manager that can be used to limit the amount of time spent waiting on something.

delay can either be `None`, or a float/int number of seconds to wait. If *delay* is `None`, no time limit will be applied; this can be useful if the delay is unknown when the context manager is created.

In either case, the context manager can be rescheduled after creation using **`Timeout.reschedule()`**.

Example:

```
async def main():
    async with asyncio.timeout(10):
        await long_running_task()
```

If `long_running_task` takes more than 10 seconds to complete, the context manager will cancel the current task and handle the resulting **`asyncio.CancelledError`** internally, transforming it into an **`asyncio.TimeoutError`** which can be caught and handled.

Note

The **`asyncio.timeout()`** context manager is what transforms the **`asyncio.CancelledError`** into an **`asyncio.TimeoutError`**, which means the **`asyncio.TimeoutError`** can only be caught *outside* of the context manager.

Example of catching **`asyncio.TimeoutError`**:

```
async def main():
    try:
        async with asyncio.timeout(10):
            await long_running_task()
    except TimeoutError:
        print("The long operation timed out, but we

    print("This statement will run regardless.")
```

The context manager produced by **`asyncio.timeout()`** can be rescheduled to a different deadline and inspected.

class asyncio.Timeout

An asynchronous context manager that limits time spent inside of it.

New in version 3.11.

when() → float | None

Return the current deadline, or `None` if the current deadline is not set.

The deadline is a float, consistent with the time returned by **`loop.time()`**.

reschedule(*when: float | None*)

Change the time the timeout will trigger.

If *when* is `None`, any current deadline will be removed, and the context manager will wait indefinitely.

If *when* is a float, it is set as the new deadline.

if *when* is in the past, the timeout will trigger on the next iteration of the event loop.

expired() → bool

Return whether the context manager has exceeded its deadline (expired).

Example:

```
async def main():
    try:
        # We do not know the timeout when starting,
        async with asyncio.timeout(None) as cm:
            # We know the timeout now, so we resche
```

```
            new_deadline = get_running_loop().time(
            cm.reschedule(new_deadline)

            await long_running_task()
    except TimeoutError:
        pass

    if cm.expired:
        print("Looks like we haven't finished on ti
```

Timeout context managers can be safely nested.

New in version 3.11.

coroutine asyncio.timeout_at(*when*)

Similar to `asyncio.timeout()`, except *when* is the absolute time to stop waiting, or `None`.

Example:

```
async def main():
    loop = get_running_loop()
    deadline = loop.time() + 20
    try:
        async with asyncio.timeout_at(deadline):
            await long_running_task()
    except TimeoutError:
        print("The long operation timed out, but we

    print("This statement will run regardless.")
```

New in version 3.11.

coroutine asyncio.wait_for(*aw*, *timeout*)

Wait for the *aw* awaitable to complete with a timeout.

If *aw* is a coroutine it is automatically scheduled as a Task.

timeout can either be `None` or a float or int number of

seconds to wait for. If *timeout* is `None`, block until the future completes.

If a timeout occurs, it cancels the task and raises **`TimeoutError`**.

To avoid the task **`cancellation`**, wrap it in **`shield()`**.

The function will wait until the future is actually cancelled, so the total wait time may exceed the *timeout*. If an exception happens during cancellation, it is propagated.

If the wait is cancelled, the future *aw* is also cancelled.

Changed in version 3.10: Removed the *loop* parameter.

Example:

```
async def eternity():
    # Sleep for one hour
    await asyncio.sleep(3600)
    print('yay!')

async def main():
    # Wait for at most 1 second
    try:
        await asyncio.wait_for(eternity(), timeout=
    except TimeoutError:
        print('timeout!')

asyncio.run(main())

# Expected output:
#
#     timeout!
```

Changed in version 3.7: When *aw* is cancelled due to a timeout, `wait_for` waits for *aw* to be cancelled. Previously, it raised **`TimeoutError`** immediately.

Changed in version 3.10: Removed the *loop* parameter.

Waiting Primitives

coroutine asyncio.wait(*aws*, *, *timeout*=*None*, *return_when*=*ALL_COMPLETED*)

Run **Future** and **Task** instances in the *aws* iterable concurrently and block until the condition specified by *return_when*.

The *aws* iterable must not be empty.

Returns two sets of Tasks/Futures: `(done, pending)`.

Usage:

```
done, pending = await asyncio.wait(aws)
```

timeout (a float or int), if specified, can be used to control the maximum number of seconds to wait before returning.

Note that this function does not raise **TimeoutError**. Futures or Tasks that aren't done when the timeout occurs are simply returned in the second set.

return_when indicates when this function should return. It must be one of the following constants:

Constant	Description
FIRST_COMPLETED	The function will return when any future finishes or is cancelled.
FIRST_EXCEPTION	The function will return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to **ALL_COMPLETED**.
ALL_COMPLETED	The function will return when all futures finish or are cancelled.

Unlike **wait_for()**, `wait()` does not cancel the futures when a timeout occurs.

Changed in version 3.10: Removed the *loop* parameter.

Changed in version 3.11: Passing coroutine objects to `wait()`

directly is forbidden.

asyncio.as_completed(*aws*, *, *timeout=None*)

Run awaitable objects in the *aws* iterable concurrently. Return an iterator of coroutines. Each coroutine returned can be awaited to get the earliest next result from the iterable of the remaining awaitables.

Raises **`TimeoutError`** if the timeout occurs before all Futures are done.

Changed in version 3.10: Removed the *loop* parameter.

Example:

```
for coro in as_completed(aws):
    earliest_result = await coro
    # ...
```

Changed in version 3.10: Removed the *loop* parameter.

Deprecated since version 3.10: Deprecation warning is emitted if not all awaitable objects in the *aws* iterable are Future-like objects and there is no running event loop.

Running in Threads

coroutine asyncio.to_thread(*func*, */*, **args*, ***kwargs*)

Asynchronously run function *func* in a separate thread.

Any *args and **kwargs supplied for this function are directly passed to *func*. Also, the current **`contextvars.Context`** is propagated, allowing context variables from the event loop thread to be accessed in the separate thread.

Return a coroutine that can be awaited to get the eventual result of *func*.

This coroutine function is primarily intended to be used for executing IO-bound functions/methods that would otherwise

block the event loop if they were run in the main thread. For example:

```
def blocking_io():
    print(f"start blocking_io at {time.strftime('%X
    # Note that time.sleep() can be replaced with a
    # IO-bound operation, such as file operations.
    time.sleep(1)
    print(f"blocking_io complete at {time.strftime(

async def main():
    print(f"started main at {time.strftime('%X')}")

    await asyncio.gather(
        asyncio.to_thread(blocking_io),
        asyncio.sleep(1))

    print(f"finished main at {time.strftime('%X')}"

asyncio.run(main())

# Expected output:
#
# started main at 19:50:53
# start blocking_io at 19:50:53
# blocking_io complete at 19:50:54
# finished main at 19:50:54
```

Directly calling `blocking_io()` in any coroutine would block the event loop for its duration, resulting in an additional 1 second of run time. Instead, by using `asyncio.to_thread()`, we can run it in a separate thread without blocking the event loop.

Note

Due to the GIL, `asyncio.to_thread()` can typically only be used to make IO-bound functions non-blocking. However, for extension modules that release the GIL or

alternative Python implementations that don't have one, `asyncio.to_thread()` can also be used for CPU-bound functions.

New in version 3.9.

Scheduling From Other Threads

asyncio.run_coroutine_threadsafe(*coro*, *loop*)

Submit a coroutine to the given event loop. Thread-safe.

Return a **`concurrent.futures.Future`** to wait for the result from another OS thread.

This function is meant to be called from a different OS thread than the one where the event loop is running. Example:

```
# Create a coroutine
coro = asyncio.sleep(1, result=3)

# Submit the coroutine to a given loop
future = asyncio.run_coroutine_threadsafe(coro, loo

# Wait for the result with an optional timeout argu
assert future.result(timeout) == 3
```

If an exception is raised in the coroutine, the returned Future will be notified. It can also be used to cancel the task in the event loop:

```
try:
    result = future.result(timeout)
except TimeoutError:
    print('The coroutine took too long, cancelling
    future.cancel()
except Exception as exc:
    print(f'The coroutine raised an exception: {exc
else:
    print(f'The coroutine returned: {result!r}')
```

See the concurrency and multithreading section of the documentation.

Unlike other asyncio functions this function requires the *loop* argument to be passed explicitly.

New in version 3.5.1.

Introspection

asyncio.current_task(*loop=None*)

Return the currently running **Task** instance, or `None` if no task is running.

If *loop* is `None` **get_running_loop()** is used to get the current loop.

New in version 3.7.

asyncio.all_tasks(*loop=None*)

Return a set of not yet finished **Task** objects run by the loop.

If *loop* is `None`, **get_running_loop()** is used for getting current loop.

New in version 3.7.

Task Object

class asyncio.Task(*coro*, *, *loop=None*, *name=None*)

A **Future-like** object that runs a Python coroutine. Not thread-safe.

Tasks are used to run coroutines in event loops. If a coroutine awaits on a Future, the Task suspends the execution of the coroutine and waits for the completion of the Future. When the Future is *done*, the execution of the wrapped coroutine resumes.

Event loops use cooperative scheduling: an event loop runs one Task at a time. While a Task awaits for the completion of a Future, the event loop runs other Tasks, callbacks, or performs IO operations.

Use the high-level **asyncio.create_task()** function to create Tasks, or the low-level **loop.create_task()** or **ensure_future()** functions. Manual instantiation of Tasks is discouraged.

To cancel a running Task use the **cancel()** method. Calling it will cause the Task to throw a **CancelledError** exception into the wrapped coroutine. If a coroutine is awaiting on a Future object during cancellation, the Future object will be cancelled.

cancelled() can be used to check if the Task was cancelled. The method returns `True` if the wrapped coroutine did not suppress the **CancelledError** exception and was actually cancelled.

asyncio.Task inherits from **Future** all of its APIs except **Future.set_result()** and **Future.set_exception()**.

Tasks support the **contextvars** module. When a Task is created it copies the current context and later runs its coroutine in the copied context.

Changed in version 3.7: Added support for the **contextvars** module.

Changed in version 3.8: Added the *name* parameter.

Deprecated since version 3.10: Deprecation warning is emitted if *loop* is not specified and there is no running event loop.

done()

Return `True` if the Task is *done*.

A Task is *done* when the wrapped coroutine either returned a value, raised an exception, or the Task was

cancelled.

result()

Return the result of the Task.

If the Task is *done*, the result of the wrapped coroutine is returned (or if the coroutine raised an exception, that exception is re-raised.)

If the Task has been *cancelled*, this method raises a **`CancelledError`** exception.

If the Task's result isn't yet available, this method raises a **`InvalidStateError`** exception.

exception()

Return the exception of the Task.

If the wrapped coroutine raised an exception that exception is returned. If the wrapped coroutine returned normally this method returns `None`.

If the Task has been *cancelled*, this method raises a **`CancelledError`** exception.

If the Task isn't *done* yet, this method raises an **`InvalidStateError`** exception.

add_done_callback(*callback*, *, *context*=*None*)

Add a callback to be run when the Task is *done*.

This method should only be used in low-level callback-based code.

See the documentation of **`Future.add_done_callback()`** for more details.

remove_done_callback(*callback*)

Remove *callback* from the callbacks list.

This method should only be used in low-level callback-based code.

See the documentation of `Future.remove_done_callback()` for more details.

get_stack(*, *limit=None*)

Return the list of stack frames for this Task.

If the wrapped coroutine is not done, this returns the stack where it is suspended. If the coroutine has completed successfully or was cancelled, this returns an empty list. If the coroutine was terminated by an exception, this returns the list of traceback frames.

The frames are always ordered from oldest to newest.

Only one stack frame is returned for a suspended coroutine.

The optional *limit* argument sets the maximum number of frames to return; by default all available frames are returned. The ordering of the returned list differs depending on whether a stack or a traceback is returned: the newest frames of a stack are returned, but the oldest frames of a traceback are returned. (This matches the behavior of the traceback module.)

print_stack(*, *limit=None*, *file=None*)

Print the stack or traceback for this Task.

This produces output similar to that of the traceback module for the frames retrieved by `get_stack()`.

The *limit* argument is passed to `get_stack()` directly.

The *file* argument is an I/O stream to which the output is written; by default output is written to `sys.stderr`.

get_coro()

Return the coroutine object wrapped by the **Task**.

New in version 3.8.

get_name()

Return the name of the Task.

If no name has been explicitly assigned to the Task, the default asyncio Task implementation generates a default name during instantiation.

New in version 3.8.

set_name(*value*)

Set the name of the Task.

The *value* argument can be any object, which is then converted to a string.

In the default Task implementation, the name will be visible in the **repr()** output of a task object.

New in version 3.8.

cancel(*msg=None*)

Request the Task to be cancelled.

This arranges for a **CancelledError** exception to be thrown into the wrapped coroutine on the next cycle of the event loop.

The coroutine then has a chance to clean up or even deny the request by suppressing the exception with a **try** … … `except CancelledError` … **finally** block. Therefore, unlike **Future.cancel()**, **Task.cancel()** does not guarantee that the Task will be cancelled, although suppressing cancellation completely is not common and is actively discouraged.

Changed in version 3.9: Added the *msg* parameter.

Changed in version 3.11: The `msg` parameter is propagated from cancelled task to its awaiter.

The following example illustrates how coroutines can intercept the cancellation request:

```
async def cancel_me():
    print('cancel_me(): before sleep')

    try:
        # Wait for 1 hour
        await asyncio.sleep(3600)
    except asyncio.CancelledError:
        print('cancel_me(): cancel sleep')
        raise
    finally:
        print('cancel_me(): after sleep')

async def main():
    # Create a "cancel_me" Task
    task = asyncio.create_task(cancel_me())

    # Wait for 1 second
    await asyncio.sleep(1)

    task.cancel()
    try:
        await task
    except asyncio.CancelledError:
        print("main(): cancel_me is cancelled n

asyncio.run(main())

# Expected output:
#
#     cancel_me(): before sleep
#     cancel_me(): cancel sleep
```

```
#     cancel_me(): after sleep
#     main(): cancel_me is cancelled now
```

cancelled()

Return `True` if the Task is *cancelled*.

The Task is *cancelled* when the cancellation was requested with **`cancel()`** and the wrapped coroutine propagated the **`CancelledError`** exception thrown into it.

uncancel()

Decrement the count of cancellation requests to this Task.

Returns the remaining number of cancellation requests.

Note that once execution of a cancelled task completed, further calls to **`uncancel()`** are ineffective.

New in version 3.11.

This method is used by asyncio's internals and isn't expected to be used by end-user code. In particular, if a Task gets successfully uncancelled, this allows for elements of structured concurrency like Task Groups and **`asyncio.timeout()`** to continue running, isolating cancellation to the respective structured block. For example:

```
async def make_request_with_timeout():
    try:
        async with asyncio.timeout(1):
            # Structured block affected by the
            await make_request()
            await make_another_request()
    except TimeoutError:
        log("There was a timeout")
    # Outer code not affected by the timeout:
```

```
await unrelated_code()
```

While the block with `make_request()` and `make_another_request()` might get cancelled due to the timeout, `unrelated_code()` should continue running even in case of the timeout. This is implemented with **`uncancel()`**. **`TaskGroup`** context managers use **`uncancel()`** in a similar fashion.

cancelling()

Return the number of pending cancellation requests to this Task, i.e., the number of calls to **`cancel()`** less the number of **`uncancel()`** calls.

Note that if this number is greater than zero but the Task is still executing, **`cancelled()`** will still return `False`. This is because this number can be lowered by calling **`uncancel()`**, which can lead to the task not being cancelled after all if the cancellation requests go down to zero.

This method is used by asyncio's internals and isn't expected to be used by end-user code. See **`uncancel()`** for more details.

New in version 3.11.

Streams

Source code: Lib/asyncio/streams.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/streams.py]

Streams are high-level async/await-ready primitives to work with network connections. Streams allow sending and receiving data without using callbacks or low-level protocols and transports.

Here is an example of a TCP echo client written using asyncio streams:

```
import asyncio

async def tcp_echo_client(message):
    reader, writer = await asyncio.open_connection(
        '127.0.0.1', 8888)

    print(f'Send: {message!r}')
    writer.write(message.encode())
    await writer.drain()

    data = await reader.read(100)
    print(f'Received: {data.decode()!r}')

    print('Close the connection')
    writer.close()
    await writer.wait_closed()

asyncio.run(tcp_echo_client('Hello World!'))
```

See also the Examples section below.

Stream Functions

The following top-level asyncio functions can be used to create and work with streams:

coroutine asyncio.open_connection(*host=None*, *port=None*, ***, *limit=None*, *ssl=None*, *family=0*, *proto=0*, *flags=0*, *sock=None*, *local_addr=None*, *server_hostname=None*, *ssl_handshake_timeout=None*, *happy_eyeballs_delay=None*, *interleave=None*)

Establish a network connection and return a pair of `(reader, writer)` objects.

The returned *reader* and *writer* objects are instances of **`StreamReader`** and **`StreamWriter`** classes.

limit determines the buffer size limit used by the returned **`StreamReader`** instance. By default the *limit* is set to 64 KiB.

The rest of the arguments are passed directly to **`loop.create_connection()`**.

Note

The *sock* argument transfers ownership of the socket to the **`StreamWriter`** created. To close the socket, call its **`close()`** method.

Changed in version 3.7: Added the *ssl_handshake_timeout* parameter.

New in version 3.8: Added *happy_eyeballs_delay* and *interleave* parameters.

Changed in version 3.10: Removed the *loop* parameter.

coroutine asyncio.start_server(*client_connected_cb*, *host=None*, *port=None*, ***, *limit=None*, *family=socket.AF_UNSPEC*, *flags=socket.AI_PASSIVE*, *sock=None*, *backlog=100*, *ssl=None*, *reuse_address=None*, *reuse_port=None*, *ssl_handshake_timeout=None*, *start_serving=True*)

Start a socket server.

The *client_connected_cb* callback is called whenever a new client connection is established. It receives a `(reader, writer)` pair as two arguments, instances of the **`StreamReader`** and **`StreamWriter`** classes.

client_connected_cb can be a plain callable or a coroutine function; if it is a coroutine function, it will be automatically scheduled as a **`Task`**.

limit determines the buffer size limit used by the returned **`StreamReader`** instance. By default the *limit* is set to 64 KiB.

The rest of the arguments are passed directly to **`loop.create_server()`**.

Note

The *sock* argument transfers ownership of the socket to the server created. To close the socket, call the server's **`close()`** method.

Changed in version 3.7: Added the *ssl_handshake_timeout* and *start_serving* parameters.

Changed in version 3.10: Removed the *loop* parameter.

Unix Sockets

coroutine asyncio.open_unix_connection(*path=None*, *, *limit=None*, *ssl=None*, *sock=None*, *server_hostname=None*, *ssl_handshake_timeout=None*)

Establish a Unix socket connection and return a pair of `(reader, writer)`.

Similar to **`open_connection()`** but operates on Unix sockets.

See also the documentation of **loop.create_unix_connection()**.

Note

The *sock* argument transfers ownership of the socket to the **StreamWriter** created. To close the socket, call its **close()** method.

Availability: Unix.

Changed in version 3.7: Added the *ssl_handshake_timeout* parameter. The *path* parameter can now be a path-like object

Changed in version 3.10: Removed the *loop* parameter.

coroutine asyncio.start_unix_server(*client_connected_cb*, *path=None*, ***, *limit=None*, *sock=None*, *backlog=100*, *ssl=None*, *ssl_handshake_timeout=None*, *start_serving=True*)

Start a Unix socket server.

Similar to **start_server()** but works with Unix sockets.

See also the documentation of **loop.create_unix_server()**.

Note

The *sock* argument transfers ownership of the socket to the server created. To close the socket, call the server's **close()** method.

Availability: Unix.

Changed in version 3.7: Added the *ssl_handshake_timeout* and *start_serving* parameters. The *path* parameter can now be a path-like object.

Changed in version 3.10: Removed the *loop* parameter.

StreamReader

class asyncio.StreamReader

Represents a reader object that provides APIs to read data from the IO stream. As an asynchronous iterable, the object supports the **`async for`** statement.

It is not recommended to instantiate *StreamReader* objects directly; use **`open_connection()`** and **`start_server()`** instead.

coroutine read(*n* = *-1*)

Read up to *n* bytes. If *n* is not provided, or set to `-1`, read until EOF and return all read bytes.

If EOF was received and the internal buffer is empty, return an empty `bytes` object.

coroutine readline()

Read one line, where "line" is a sequence of bytes ending with `\n`.

If EOF is received and `\n` was not found, the method returns partially read data.

If EOF is received and the internal buffer is empty, return an empty `bytes` object.

coroutine readexactly(*n*)

Read exactly *n* bytes.

Raise an **`IncompleteReadError`** if EOF is reached before *n* can be read. Use the **`IncompleteReadError.partial`** attribute to get the partially read data.

coroutine readuntil(*separator* = *b'\n'*)

Read data from the stream until *separator* is found.

On success, the data and separator will be removed from the internal buffer (consumed). Returned data will include the separator at the end.

If the amount of data read exceeds the configured stream limit, a **LimitOverrunError** exception is raised, and the data is left in the internal buffer and can be read again.

If EOF is reached before the complete separator is found, an **IncompleteReadError** exception is raised, and the internal buffer is reset. The **IncompleteReadError.partial** attribute may contain a portion of the separator.

New in version 3.5.2.

at_eof()

Return `True` if the buffer is empty and **feed_eof()** was called.

StreamWriter

class asyncio.StreamWriter

Represents a writer object that provides APIs to write data to the IO stream.

It is not recommended to instantiate *StreamWriter* objects directly; use **open_connection()** and **start_server()** instead.

write(*data*)

The method attempts to write the *data* to the underlying socket immediately. If that fails, the data is queued in an internal write buffer until it can be sent.

The method should be used along with the `drain()` method:

```
stream.write(data)
await stream.drain()
```

writelines(*data*)

The method writes a list (or any iterable) of bytes to the underlying socket immediately. If that fails, the data is queued in an internal write buffer until it can be sent.

The method should be used along with the `drain()` method:

```
stream.writelines(lines)
await stream.drain()
```

close()

The method closes the stream and the underlying socket.

The method should be used along with the `wait_closed()` method:

```
stream.close()
await stream.wait_closed()
```

can_write_eof()

Return `True` if the underlying transport supports the **`write_eof()`** method, `False` otherwise.

write_eof()

Close the write end of the stream after the buffered write data is flushed.

transport

Return the underlying asyncio transport.

get_extra_info(*name*, *default*=*None*)

Access optional transport information; see **`BaseTransport.get_extra_info()`** for details.

coroutine drain()

Wait until it is appropriate to resume writing to the stream. Example:

```
writer.write(data)
await writer.drain()
```

This is a flow control method that interacts with the underlying IO write buffer. When the size of the buffer reaches the high watermark, *drain()* blocks until the size of the buffer is drained down to the low watermark and writing can be resumed. When there is nothing to wait for, the **`drain()`** returns immediately.

coroutine start_tls(*sslcontext*, *, *server_hostname=None*, *ssl_handshake_timeout=None*)

Upgrade an existing stream-based connection to TLS.

Parameters:

- *sslcontext*: a configured instance of **`SSLContext`**.
- *server_hostname*: sets or overrides the host name that the target server's certificate will be matched against.
- *ssl_handshake_timeout* is the time in seconds to wait for the TLS handshake to complete before aborting the connection. `60.0` seconds if `None` (default).

New in version 3.11.

is_closing()

Return `True` if the stream is closed or in the process of being closed.

New in version 3.7.

coroutine wait_closed()

Wait until the stream is closed.

Should be called after `close()` to wait until the underlying connection is closed.

New in version 3.7.

Examples

TCP echo client using streams

TCP echo client using the `asyncio.open_connection()` function:

```
import asyncio

async def tcp_echo_client(message):
    reader, writer = await asyncio.open_connection(
        '127.0.0.1', 8888)

    print(f'Send: {message!r}')
    writer.write(message.encode())
    await writer.drain()

    data = await reader.read(100)
    print(f'Received: {data.decode()!r}')

    print('Close the connection')
    writer.close()

asyncio.run(tcp_echo_client('Hello World!'))
```

See also

The TCP echo client protocol example uses the low-level `loop.create_connection()` method.

TCP echo server using streams

TCP echo server using the **`asyncio.start_server()`** function:

```
import asyncio

async def handle_echo(reader, writer):
    data = await reader.read(100)
    message = data.decode()
    addr = writer.get_extra_info('peername')

    print(f"Received {message!r} from {addr!r}")

    print(f"Send: {message!r}")
    writer.write(data)
    await writer.drain()

    print("Close the connection")
    writer.close()

async def main():
    server = await asyncio.start_server(
        handle_echo, '127.0.0.1', 8888)

    addrs = ', '.join(str(sock.getsockname()) for sock i
    print(f'Serving on {addrs}')

    async with server:
        await server.serve_forever()

asyncio.run(main())
```

See also

The TCP echo server protocol example uses the **`loop.create_server()`** method.

Get HTTP headers

Simple example querying HTTP headers of the URL passed on the command line:

```
import asyncio
import urllib.parse
import sys

async def print_http_headers(url):
    url = urllib.parse.urlsplit(url)
    if url.scheme == 'https':
        reader, writer = await asyncio.open_connection(
            url.hostname, 443, ssl=True)
    else:
        reader, writer = await asyncio.open_connection(
            url.hostname, 80)

    query = (
        f"HEAD {url.path or '/'} HTTP/1.0\r\n"
        f"Host: {url.hostname}\r\n"
        f"\r\n"
    )

    writer.write(query.encode('latin-1'))
    while True:
        line = await reader.readline()
        if not line:
            break

        line = line.decode('latin1').rstrip()
        if line:
            print(f'HTTP header> {line}')

    # Ignore the body, close the socket
    writer.close()

url = sys.argv[1]
asyncio.run(print_http_headers(url))
```

Usage:

```
python example.py http://example.com/path/page.html
```

or with HTTPS:

```
python example.py https://example.com/path/page.html
```

Register an open socket to wait for data using streams

Coroutine waiting until a socket receives data using the **`open_connection()`** function:

```
import asyncio
import socket

async def wait_for_data():
    # Get a reference to the current event loop because
    # we want to access low-level APIs.
    loop = asyncio.get_running_loop()

    # Create a pair of connected sockets.
    rsock, wsock = socket.socketpair()

    # Register the open socket to wait for data.
    reader, writer = await asyncio.open_connection(sock=

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())

    # Wait for data
    data = await reader.read(100)

    # Got data, we are done: close the socket
    print("Received:", data.decode())
    writer.close()

    # Close the second socket
    wsock.close()

asyncio.run(wait_for_data())
```

See also

The register an open socket to wait for data using a protocol example uses a low-level protocol and the `loop.create_connection()` method.

The watch a file descriptor for read events example uses the low-level `loop.add_reader()` method to watch a file descriptor.

Synchronization Primitives

Source code: Lib/asyncio/locks.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/locks.py]

---

asyncio synchronization primitives are designed to be similar to those of the `threading` module with two important caveats:

- asyncio primitives are not thread-safe, therefore they should not be used for OS thread synchronization (use `threading` for that);
- methods of these synchronization primitives do not accept the *timeout* argument; use the `asyncio.wait_for()` function to perform operations with timeouts.

asyncio has the following basic synchronization primitives:

- `Lock`
- `Event`
- `Condition`
- `Semaphore`
- `BoundedSemaphore`
- `Barrier`

Lock

class asyncio.Lock

Implements a mutex lock for asyncio tasks. Not thread-safe.

An asyncio lock can be used to guarantee exclusive access to a shared resource.

The preferred way to use a Lock is an `async with` statement:

```
lock = asyncio.Lock()

# ... later
async with lock:
    # access shared state
```

which is equivalent to:

```
lock = asyncio.Lock()

# ... later
await lock.acquire()
try:
    # access shared state
finally:
    lock.release()
```

Changed in version 3.10: Removed the *loop* parameter.

coroutine acquire()

Acquire the lock.

This method waits until the lock is *unlocked*, sets it to *locked* and returns `True`.

When more than one coroutine is blocked in **`acquire()`** waiting for the lock to be unlocked, only one coroutine eventually proceeds.

Acquiring a lock is *fair*: the coroutine that proceeds will be the first coroutine that started waiting on the lock.

release()

Release the lock.

When the lock is *locked*, reset it to *unlocked* and return.

If the lock is *unlocked*, a **`RuntimeError`** is raised.

locked()

Return `True` if the lock is *locked*.

Event

class asyncio.Event

An event object. Not thread-safe.

An asyncio event can be used to notify multiple asyncio tasks that some event has happened.

An Event object manages an internal flag that can be set to *true* with the **`set()`** method and reset to *false* with the **`clear()`** method. The **`wait()`** method blocks until the flag is set to *true*. The flag is set to *false* initially.

Changed in version 3.10: Removed the *loop* parameter.

Example:

```
async def waiter(event):
    print('waiting for it ...')
    await event.wait()
    print('... got it!')

async def main():
    # Create an Event object.
    event = asyncio.Event()

    # Spawn a Task to wait until 'event' is set.
    waiter_task = asyncio.create_task(waiter(event))

    # Sleep for 1 second and set the event.
    await asyncio.sleep(1)
    event.set()

    # Wait until the waiter task is finished.
    await waiter_task

asyncio.run(main())
```

coroutine wait()

Wait until the event is set.

If the event is set, return `True` immediately. Otherwise block until another task calls **`set()`**.

set()

Set the event.

All tasks waiting for event to be set will be immediately awakened.

clear()

Clear (unset) the event.

Tasks awaiting on **`wait()`** will now block until the **`set()`** method is called again.

is_set()

Return `True` if the event is set.

Condition

class asyncio.Condition(*lock=None*)

A Condition object. Not thread-safe.

An asyncio condition primitive can be used by a task to wait for some event to happen and then get exclusive access to a shared resource.

In essence, a Condition object combines the functionality of an **`Event`** and a **`Lock`**. It is possible to have multiple Condition objects share one Lock, which allows coordinating exclusive access to a shared resource between different tasks interested in particular states of that shared resource.

The optional *lock* argument must be a **`Lock`** object or `None`. In the latter case a new Lock object is created automatically.

Changed in version 3.10: Removed the *loop* parameter.

The preferred way to use a Condition is an **async with** statement:

```
cond = asyncio.Condition()

# ... later
async with cond:
    await cond.wait()
```

which is equivalent to:

```
cond = asyncio.Condition()

# ... later
await cond.acquire()
try:
    await cond.wait()
finally:
    cond.release()
```

coroutine acquire()

Acquire the underlying lock.

This method waits until the underlying lock is *unlocked*, sets it to *locked* and returns `True`.

notify(*n=1*)

Wake up at most *n* tasks (1 by default) waiting on this condition. The method is no-op if no tasks are waiting.

The lock must be acquired before this method is called and released shortly after. If called with an *unlocked* lock a **RuntimeError** error is raised.

locked()

Return `True` if the underlying lock is acquired.

notify_all()

Wake up all tasks waiting on this condition.

This method acts like **notify()**, but wakes up all waiting tasks.

The lock must be acquired before this method is called and released shortly after. If called with an *unlocked* lock a **RuntimeError** error is raised.

release()

Release the underlying lock.

When invoked on an unlocked lock, a **RuntimeError** is raised.

coroutine wait()

Wait until notified.

If the calling task has not acquired the lock when this method is called, a **RuntimeError** is raised.

This method releases the underlying lock, and then blocks until it is awakened by a **notify()** or **notify_all()** call. Once awakened, the Condition re-acquires its lock and this method returns `True`.

coroutine wait_for(*predicate*)

Wait until a predicate becomes *true*.

The predicate must be a callable which result will be interpreted as a boolean value. The final value is the return value.

Semaphore

class asyncio.Semaphore(*value=1*)

A Semaphore object. Not thread-safe.

A semaphore manages an internal counter which is decremented by each **`acquire()`** call and incremented by each **`release()`** call. The counter can never go below zero; when **`acquire()`** finds that it is zero, it blocks, waiting until some task calls **`release()`**.

The optional *value* argument gives the initial value for the internal counter (`1` by default). If the given value is less than `0` a **`ValueError`** is raised.

Changed in version 3.10: Removed the *loop* parameter.

The preferred way to use a Semaphore is an **`async with`** statement:

```
sem = asyncio.Semaphore(10)

# ... later
async with sem:
    # work with shared resource
```

which is equivalent to:

```
sem = asyncio.Semaphore(10)

# ... later
await sem.acquire()
try:
    # work with shared resource
finally:
    sem.release()
```

coroutine acquire()

Acquire a semaphore.

If the internal counter is greater than zero, decrement it by one and return `True` immediately. If it is zero, wait until a **`release()`** is called and return `True`.

locked()

Returns `True` if semaphore can not be acquired immediately.

release()

Release a semaphore, incrementing the internal counter by one. Can wake up a task waiting to acquire the semaphore.

Unlike **`BoundedSemaphore`**, **`Semaphore`** allows making more `release()` calls than `acquire()` calls.

BoundedSemaphore

class asyncio.BoundedSemaphore(*value=1*)

A bounded semaphore object. Not thread-safe.

Bounded Semaphore is a version of **`Semaphore`** that raises a **`ValueError`** in **`release()`** if it increases the internal counter above the initial *value*.

Changed in version 3.10: Removed the *loop* parameter.

Barrier

class asyncio.Barrier(*parties*)

A barrier object. Not thread-safe.

A barrier is a simple synchronization primitive that allows to block until *parties* number of tasks are waiting on it. Tasks can wait on the **`wait()`** method and would be blocked until the specified number of tasks end up waiting on **`wait()`**. At that point all of the waiting tasks would unblock simultaneously.

`async with` can be used as an alternative to awaiting on **`wait()`**.

The barrier can be reused any number of times.

Example:

```
async def example_barrier():
   # barrier with 3 parties
   b = asyncio.Barrier(3)

   # create 2 new waiting tasks
   asyncio.create_task(b.wait())
   asyncio.create_task(b.wait())

   await asyncio.sleep(0)
   print(b)

   # The third .wait() call passes the barrier
   await b.wait()
   print(b)
   print("barrier passed")

   await asyncio.sleep(0)
   print(b)

asyncio.run(example_barrier())
```

Result of this example is:

```
<asyncio.locks.Barrier object at 0x... [filling, wa
<asyncio.locks.Barrier object at 0x... [draining, w
barrier passed
<asyncio.locks.Barrier object at 0x... [filling, wa
```

New in version 3.11.

coroutine wait()

Pass the barrier. When all the tasks party to the barrier have called this function, they are all unblocked simultaneously.

When a waiting or blocked task in the barrier is

cancelled, this task exits the barrier which stays in the same state. If the state of the barrier is “filling”, the number of waiting task decreases by 1.

The return value is an integer in the range of 0 to `parties-1`, different for each task. This can be used to select a task to do some special housekeeping, e.g.:

```
...
async with barrier as position:
   if position == 0:
      # Only one task prints this
      print('End of *draining phase*')
```

This method may raise a **`BrokenBarrierError`** exception if the barrier is broken or reset while a task is waiting. It could raise a **`CancelledError`** if a task is cancelled.

coroutine reset()

Return the barrier to the default, empty state. Any tasks waiting on it will receive the **`BrokenBarrierError`** exception.

If a barrier is broken it may be better to just leave it and create a new one.

coroutine abort()

Put the barrier into a broken state. This causes any active or future calls to **`wait()`** to fail with the **`BrokenBarrierError`**. Use this for example if one of the tasks needs to abort, to avoid infinite waiting tasks.

parties

The number of tasks required to pass the barrier.

n_waiting

The number of tasks currently waiting in the barrier while filling.

broken

A boolean that is `True` if the barrier is in the broken state.

exception asyncio.BrokenBarrierError

This exception, a subclass of **`RuntimeError`**, is raised when the **`Barrier`** object is reset or broken.

Changed in version 3.9: Acquiring a lock using `await lock` or `yield from lock` and/or **`with`** statement (`with await lock`, `with (yield from lock)`) was removed. Use `async with lock` instead.

Subprocesses

Source code: Lib/asyncio/subprocess.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/subprocess.py], Lib/asyncio/base_subprocess.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/base_subprocess.py]

This section describes high-level async/await asyncio APIs to create and manage subprocesses.

Here's an example of how asyncio can run a shell command and obtain its result:

```
import asyncio

async def run(cmd):
    proc = await asyncio.create_subprocess_shell(
        cmd,
        stdout=asyncio.subprocess.PIPE,
        stderr=asyncio.subprocess.PIPE)

    stdout, stderr = await proc.communicate()

    print(f'[{cmd!r} exited with {proc.returncode}]')
    if stdout:
        print(f'[stdout]\n{stdout.decode()}')
    if stderr:
        print(f'[stderr]\n{stderr.decode()}')

asyncio.run(run('ls /zzz'))
```

will print:

```
['ls /zzz' exited with 1]
[stderr]
```

```
ls: /zzz: No such file or directory
```

Because all asyncio subprocess functions are asynchronous and asyncio provides many tools to work with such functions, it is easy to execute and monitor multiple subprocesses in parallel. It is indeed trivial to modify the above example to run several commands simultaneously:

```
async def main():
    await asyncio.gather(
        run('ls /zzz'),
        run('sleep 1; echo "hello"'))

asyncio.run(main())
```

See also the Examples subsection.

Creating Subprocesses

coroutine asyncio.create_subprocess_exec(*program*, **args*, *stdin=None*, *stdout=None*, *stderr=None*, *limit=None*, ***kwds*)

Create a subprocess.

The *limit* argument sets the buffer limit for **StreamReader** wrappers for **Process.stdout** and **Process.stderr** (if **subprocess.PIPE** is passed to *stdout* and *stderr* arguments).

Return a **Process** instance.

See the documentation of **loop.subprocess_exec()** for other parameters.

Changed in version 3.10: Removed the *loop* parameter.

coroutine asyncio.create_subprocess_shell(*cmd*, *stdin=None*, *stdout=None*, *stderr=None*, *limit=None*, ***kwds*)

Run the *cmd* shell command.

The *limit* argument sets the buffer limit for **StreamReader**

wrappers for `Process.stdout` and `Process.stderr` (if `subprocess.PIPE` is passed to *stdout* and *stderr* arguments).

Return a `Process` instance.

See the documentation of `loop.subprocess_shell()` for other parameters.

Important

It is the application's responsibility to ensure that all whitespace and special characters are quoted appropriately to avoid shell injection [https://en.wikipedia.org/wiki/Shell_injection#Shell_injection] vulnerabilities. The `shlex.quote()` function can be used to properly escape whitespace and special shell characters in strings that are going to be used to construct shell commands.

Changed in version 3.10: Removed the *loop* parameter.

Note

Subprocesses are available for Windows if a `ProactorEventLoop` is used. See Subprocess Support on Windows for details.

See also

asyncio also has the following *low-level* APIs to work with subprocesses: `loop.subprocess_exec()`, `loop.subprocess_shell()`, `loop.connect_read_pipe()`, `loop.connect_write_pipe()`, as well as the Subprocess Transports and Subprocess Protocols.

Constants

asyncio.subprocess.PIPE

Can be passed to the *stdin*, *stdout* or *stderr* parameters.

If *PIPE* is passed to *stdin* argument, the **`Process.stdin`** attribute will point to a **`StreamWriter`** instance.

If *PIPE* is passed to *stdout* or *stderr* arguments, the **`Process.stdout`** and **`Process.stderr`** attributes will point to **`StreamReader`** instances.

asyncio.subprocess.STDOUT

Special value that can be used as the *stderr* argument and indicates that standard error should be redirected into standard output.

asyncio.subprocess.DEVNULL

Special value that can be used as the *stdin*, *stdout* or *stderr* argument to process creation functions. It indicates that the special file **`os.devnull`** will be used for the corresponding subprocess stream.

Interacting with Subprocesses

Both **`create_subprocess_exec()`** and **`create_subprocess_shell()`** functions return instances of the *Process* class. *Process* is a high-level wrapper that allows communicating with subprocesses and watching for their completion.

class asyncio.subprocess.Process

An object that wraps OS processes created by the **`create_subprocess_exec()`** and **`create_subprocess_shell()`** functions.

This class is designed to have a similar API to the **`subprocess.Popen`** class, but there are some notable differences:

- unlike Popen, Process instances do not have an equivalent to the **`poll()`** method;

- the **`communicate()`** and **`wait()`** methods don't have a *timeout* parameter: use the **`wait_for()`** function;
- the **`Process.wait()`** method is asynchronous, whereas **`subprocess.Popen.wait()`** method is implemented as a blocking busy loop;
- the *universal_newlines* parameter is not supported.

This class is not thread safe.

See also the Subprocess and Threads section.

coroutine wait()

Wait for the child process to terminate.

Set and return the **`returncode`** attribute.

Note

This method can deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates so much output that it blocks waiting for the OS pipe buffer to accept more data. Use the **`communicate()`** method when using pipes to avoid this condition.

coroutine communicate(*input=None*)

Interact with process:

1. send data to *stdin* (if *input* is not `None`);
2. read data from *stdout* and *stderr*, until EOF is reached;
3. wait for process to terminate.

The optional *input* argument is the data (**`bytes`** object) that will be sent to the child process.

Return a tuple `(stdout_data, stderr_data)`.

If either **BrokenPipeError** or **ConnectionResetError** exception is raised when writing *input* into *stdin*, the exception is ignored. This condition occurs when the process exits before all data are written into *stdin*.

If it is desired to send data to the process' *stdin*, the process needs to be created with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, the process has to be created with `stdout=PIPE` and/or `stderr=PIPE` arguments.

Note, that the data read is buffered in memory, so do not use this method if the data size is large or unlimited.

send_signal(*signal*)

Sends the signal *signal* to the child process.

Note

On Windows, **SIGTERM** is an alias for **terminate()**. `CTRL_C_EVENT` and `CTRL_BREAK_EVENT` can be sent to processes started with a *creationflags* parameter which includes `CREATE_NEW_PROCESS_GROUP`.

terminate()

Stop the child process.

On POSIX systems this method sends **signal.SIGTERM** to the child process.

On Windows the Win32 API function **TerminateProcess()** is called to stop the child process.

kill()

Kill the child process.

On POSIX systems this method sends **`SIGKILL`** to the child process.

On Windows this method is an alias for **`terminate()`**.

stdin

Standard input stream (**`StreamWriter`**) or `None` if the process was created with `stdin=None`.

stdout

Standard output stream (**`StreamReader`**) or `None` if the process was created with `stdout=None`.

stderr

Standard error stream (**`StreamReader`**) or `None` if the process was created with `stderr=None`.

Warning

Use the **`communicate()`** method rather than **`process.stdin.write()`**, **`await process.stdout.read()`** or **`await process.stderr.read()`**. This avoids deadlocks due to streams pausing reading or writing and blocking the child process.

pid

Process identification number (PID).

Note that for processes created by the **`create_subprocess_shell()`** function, this attribute is the PID of the spawned shell.

returncode

Return code of the process when it exits.

A `None` value indicates that the process has not terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

Subprocess and Threads

Standard asyncio event loop supports running subprocesses from different threads by default.

On Windows subprocesses are provided by **`ProactorEventLoop`** only (default), **`SelectorEventLoop`** has no subprocess support.

On UNIX *child watchers* are used for subprocess finish waiting, see Process Watchers for more info.

Changed in version 3.8: UNIX switched to use **`ThreadedChildWatcher`** for spawning subprocesses from different threads without any limitation.

Spawning a subprocess with *inactive* current child watcher raises **`RuntimeError`**.

Note that alternative event loop implementations might have own limitations; please refer to their documentation.

See also

The Concurrency and multithreading in asyncio section.

Examples

An example using the **`Process`** class to control a subprocess and the **`StreamReader`** class to read from its standard output.

The subprocess is created by the **`create_subprocess_exec()`** function:

```
import asyncio
```

```
import sys

async def get_date():
    code = 'import datetime; print(datetime.datetime.now

    # Create the subprocess; redirect the standard outpu
    # into a pipe.
    proc = await asyncio.create_subprocess_exec(
        sys.executable, '-c', code,
        stdout=asyncio.subprocess.PIPE)

    # Read one line of output.
    data = await proc.stdout.readline()
    line = data.decode('ascii').rstrip()

    # Wait for the subprocess exit.
    await proc.wait()
    return line

date = asyncio.run(get_date())
print(f"Current date: {date}")
```

See also the same example written using low-level APIs.

Queues

Source code: Lib/asyncio/queues.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/queues.py]

---

asyncio queues are designed to be similar to classes of the **queue** module. Although asyncio queues are not thread-safe, they are designed to be used specifically in async/await code.

Note that methods of asyncio queues don't have a *timeout* parameter; use **asyncio.wait_for()** function to do queue operations with a timeout.

See also the Examples section below.

Queue

class asyncio.Queue(*maxsize=0*)

A first in, first out (FIFO) queue.

If *maxsize* is less than or equal to zero, the queue size is infinite. If it is an integer greater than `0`, then `await put()` blocks when the queue reaches *maxsize* until an item is removed by **get()**.

Unlike the standard library threading **queue**, the size of the queue is always known and can be returned by calling the **qsize()** method.

Changed in version 3.10: Removed the *loop* parameter.

This class is not thread safe.

maxsize

Number of items allowed in the queue.

empty()

Return `True` if the queue is empty, `False` otherwise.

full()

Return `True` if there are **`maxsize`** items in the queue.

If the queue was initialized with `maxsize=0` (the default), then **`full()`** never returns `True`.

coroutine get()

Remove and return an item from the queue. If queue is empty, wait until an item is available.

get_nowait()

Return an item if one is immediately available, else raise **`QueueEmpty`**.

coroutine join()

Block until all items in the queue have been received and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer coroutine calls **`task_done()`** to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, **`join()`** unblocks.

coroutine put(*item*)

Put an item into the queue. If the queue is full, wait until a free slot is available before adding the item.

put_nowait(*item*)

Put an item into the queue without blocking.

If no free slot is immediately available, raise **`QueueFull`**.

qsize()

Return the number of items in the queue.

task_done()

Indicate that a formerly enqueued task is complete.

Used by queue consumers. For each `get()` used to fetch a task, a subsequent call to `task_done()` tells the queue that the processing on the task is complete.

If a `join()` is currently blocking, it will resume when all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).

Raises `ValueError` if called more times than there were items placed in the queue.

Priority Queue

class asyncio.PriorityQueue

A variant of `Queue`; retrieves entries in priority order (lowest first).

Entries are typically tuples of the form `(priority_number, data)`.

LIFO Queue

class asyncio.LifoQueue

A variant of `Queue` that retrieves most recently added entries first (last in, first out).

Exceptions

exception asyncio.QueueEmpty

This exception is raised when the `get_nowait()` method is

called on an empty queue.

exception asyncio.QueueFull

Exception raised when the **`put_nowait()`** method is called on a queue that has reached its *maxsize*.

Examples

Queues can be used to distribute workload between several concurrent tasks:

```
import asyncio
import random
import time

async def worker(name, queue):
    while True:
        # Get a "work item" out of the queue.
        sleep_for = await queue.get()

        # Sleep for the "sleep_for" seconds.
        await asyncio.sleep(sleep_for)

        # Notify the queue that the "work item" has beer
        queue.task_done()

        print(f'{name} has slept for {sleep_for:.2f} sec

async def main():
    # Create a queue that we will use to store our "work
    queue = asyncio.Queue()

    # Generate random timings and put them into the queu
    total_sleep_time = 0
    for _ in range(20):
        sleep_for = random.uniform(0.05, 1.0)
```

```
        total_sleep_time += sleep_for
        queue.put_nowait(sleep_for)

    # Create three worker tasks to process the queue con
    tasks = []
    for i in range(3):
        task = asyncio.create_task(worker(f'worker-{i}',
        tasks.append(task)

    # Wait until the queue is fully processed.
    started_at = time.monotonic()
    await queue.join()
    total_slept_for = time.monotonic() - started_at

    # Cancel our worker tasks.
    for task in tasks:
        task.cancel()
    # Wait until all worker tasks are cancelled.
    await asyncio.gather(*tasks, return_exceptions=True)

    print('====')
    print(f'3 workers slept in parallel for {total_slept
    print(f'total expected sleep time: {total_sleep_time

asyncio.run(main())
```

Exceptions

Source code: Lib/asyncio/exceptions.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/exceptions.py]

---

exception asyncio.TimeoutError

A deprecated alias of **`TimeoutError`**, raised when the operation has exceeded the given deadline.

Changed in version 3.11: This class was made an alias of **`TimeoutError`**.

exception asyncio.CancelledError

The operation has been cancelled.

This exception can be caught to perform custom operations when asyncio Tasks are cancelled. In almost all situations the exception must be re-raised.

Changed in version 3.8: **`CancelledError`** is now a subclass of **`BaseException`**.

exception asyncio.InvalidStateError

Invalid internal state of **`Task`** or **`Future`**.

Can be raised in situations like setting a result value for a *Future* object that already has a result value set.

exception asyncio.SendfileNotAvailableError

The “sendfile” syscall is not available for the given socket or file type.

A subclass of **`RuntimeError`**.

exception asyncio.IncompleteReadError

The requested read operation did not complete fully.

Raised by the asyncio stream APIs.

This exception is a subclass of **`EOFError`**.

expected

The total number (**`int`**) of expected bytes.

partial

A string of **`bytes`** read before the end of stream was reached.

exception asyncio.LimitOverrunError

Reached the buffer size limit while looking for a separator.

Raised by the asyncio stream APIs.

consumed

The total number of to be consumed bytes.

Event Loop

Source code: Lib/asyncio/events.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/events.py], Lib/asyncio/base_events.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/base_events.py]

Preface

The event loop is the core of every asyncio application. Event loops run asynchronous tasks and callbacks, perform network IO operations, and run subprocesses.

Application developers should typically use the high-level asyncio functions, such as `asyncio.run()`, and should rarely need to reference the loop object or call its methods. This section is intended mostly for authors of lower-level code, libraries, and frameworks, who need finer control over the event loop behavior.

Obtaining the Event Loop

The following low-level functions can be used to get, set, or create an event loop:

asyncio.get_running_loop()

Return the running event loop in the current OS thread.

Raise a `RuntimeError` if there is no running event loop.

This function can only be called from a coroutine or a callback.

New in version 3.7.

asyncio.get_event_loop()

Get the current event loop.

When called from a coroutine or a callback (e.g. scheduled with call_soon or similar API), this function will always return the running event loop.

If there is no running event loop set, the function will return the result of `get_event_loop_policy().get_event_loop()` call.

Because this function has rather complex behavior (especially when custom event loop policies are in use), using the **`get_running_loop()`** function is preferred to **`get_event_loop()`** in coroutines and callbacks.

As noted above, consider using the higher-level **`asyncio.run()`** function, instead of using these lower level functions to manually create and close an event loop.

Deprecated since version 3.10: Deprecation warning is emitted if there is no current event loop. In Python 3.12 it will be an error.

Note

In Python versions 3.10.0–3.10.8 and 3.11.0 this function (and other functions which used it implicitly) emitted a **`DeprecationWarning`** if there was no running event loop, even if the current loop was set.

asyncio.set_event_loop(*loop*)

Set *loop* as the current event loop for the current OS thread.

asyncio.new_event_loop()

Create and return a new event loop object.

Note that the behaviour of **`get_event_loop()`**,

`set_event_loop()`, and `new_event_loop()` functions can be altered by setting a custom event loop policy.

Contents

This documentation page contains the following sections:

- The Event Loop Methods section is the reference documentation of the event loop APIs;
- The Callback Handles section documents the `Handle` and `TimerHandle` instances which are returned from scheduling methods such as `loop.call_soon()` and `loop.call_later()`;
- The Server Objects section documents types returned from event loop methods like `loop.create_server()`;
- The Event Loop Implementations section documents the `SelectorEventLoop` and `ProactorEventLoop` classes;
- The Examples section showcases how to work with some event loop APIs.

Event Loop Methods

Event loops have **low-level** APIs for the following:

- Running and stopping the loop
- Scheduling callbacks
- Scheduling delayed callbacks
- Creating Futures and Tasks
- Opening network connections
- Creating network servers
- Transferring files
- TLS Upgrade
- Watching file descriptors
- Working with socket objects directly
- DNS
- Working with pipes
- Unix signals
- Executing code in thread or process pools

- Error Handling API
- Enabling debug mode
- Running Subprocesses

Running and stopping the loop

loop.run_until_complete(*future*)

Run until the *future* (an instance of **`Future`**) has completed.

If the argument is a coroutine object it is implicitly scheduled to run as a **`asyncio.Task`**.

Return the Future's result or raise its exception.

loop.run_forever()

Run the event loop until **`stop()`** is called.

If **`stop()`** is called before **`run_forever()`** is called, the loop will poll the I/O selector once with a timeout of zero, run all callbacks scheduled in response to I/O events (and those that were already scheduled), and then exit.

If **`stop()`** is called while **`run_forever()`** is running, the loop will run the current batch of callbacks and then exit. Note that new callbacks scheduled by callbacks will not run in this case; instead, they will run the next time **`run_forever()`** or **`run_until_complete()`** is called.

loop.stop()

Stop the event loop.

loop.is_running()

Return `True` if the event loop is currently running.

loop.is_closed()

Return `True` if the event loop was closed.

loop.close()

Close the event loop.

The loop must not be running when this function is called. Any pending callbacks will be discarded.

This method clears all queues and shuts down the executor, but does not wait for the executor to finish.

This method is idempotent and irreversible. No other methods should be called after the event loop is closed.

coroutine loop.shutdown_asyncgens()

Schedule all currently open asynchronous generator objects to close with an **`aclose()`** call. After calling this method, the event loop will issue a warning if a new asynchronous generator is iterated. This should be used to reliably finalize all scheduled asynchronous generators.

Note that there is no need to call this function when **`asyncio.run()`** is used.

Example:

```
try:
    loop.run_forever()
finally:
    loop.run_until_complete(loop.shutdown_asyncgens
    loop.close()
```

New in version 3.6.

coroutine loop.shutdown_default_executor()

Schedule the closure of the default executor and wait for it to join all of the threads in the **`ThreadPoolExecutor`**. After calling this method, a **`RuntimeError`** will be raised if **`loop.run_in_executor()`** is called while using the default executor.

Note that there is no need to call this function when

`asyncio.run()` is used.

New in version 3.9.

Scheduling callbacks

loop.call_soon(*callback*, **args*, *context=None*)

Schedule the *callback* callback to be called with *args* arguments at the next iteration of the event loop.

Callbacks are called in the order in which they are registered. Each callback will be called exactly once.

An optional keyword-only *context* argument allows specifying a custom `contextvars.Context` for the *callback* to run in. The current context is used when no *context* is provided.

An instance of `asyncio.Handle` is returned, which can be used later to cancel the callback.

This method is not thread-safe.

loop.call_soon_threadsafe(*callback*, **args*, *context=None*)

A thread-safe variant of `call_soon()`. Must be used to schedule callbacks *from another thread*.

Raises `RuntimeError` if called on a loop that's been closed. This can happen on a secondary thread when the main application is shutting down.

See the concurrency and multithreading section of the documentation.

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** [https://peps.python.org/pep-0567/] for more details.

Note

Most `asyncio` scheduling functions don't allow passing keyword arguments. To do that, use `functools.partial()`:

```
# will schedule "print("Hello", flush=True)"
loop.call_soon(
    functools.partial(print, "Hello", flush=True))
```

Using partial objects is usually more convenient than using lambdas, as asyncio can render partial objects better in debug and error messages.

Scheduling delayed callbacks

Event loop provides mechanisms to schedule callback functions to be called at some point in the future. Event loop uses monotonic clocks to track time.

loop.call_later(*delay*, *callback*, **args*, *context=None*)

Schedule *callback* to be called after the given *delay* number of seconds (can be either an int or a float).

An instance of **`asyncio.TimerHandle`** is returned which can be used to cancel the callback.

callback will be called exactly once. If two callbacks are scheduled for exactly the same time, the order in which they are called is undefined.

The optional positional *args* will be passed to the callback when it is called. If you want the callback to be called with keyword arguments use **`functools.partial()`**.

An optional keyword-only *context* argument allows specifying a custom **`contextvars.Context`** for the *callback* to run in. The current context is used when no *context* is provided.

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** [https://peps.python.org/pep-0567/] for more details.

Changed in version 3.8: In Python 3.7 and earlier with the default event loop implementation, the *delay* could not exceed one day. This has been fixed in Python 3.8.

loop.call_at(*when*, *callback*, **args*, *context=None*)

Schedule *callback* to be called at the given absolute timestamp *when* (an int or a float), using the same time reference as `loop.time()`.

This method's behavior is the same as `call_later()`.

An instance of `asyncio.TimerHandle` is returned which can be used to cancel the callback.

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** [https://peps.python.org/pep-0567/] for more details.

Changed in version 3.8: In Python 3.7 and earlier with the default event loop implementation, the difference between *when* and the current time could not exceed one day. This has been fixed in Python 3.8.

loop.time()

Return the current time, as a `float` value, according to the event loop's internal monotonic clock.

Note

Changed in version 3.8: In Python 3.7 and earlier timeouts (relative *delay* or absolute *when*) should not exceed one day. This has been fixed in Python 3.8.

See also

The `asyncio.sleep()` function.

Creating Futures and Tasks

loop.create_future()

Create an `asyncio.Future` object attached to the event

loop.

This is the preferred way to create Futures in asyncio. This lets third-party event loops provide alternative implementations of the Future object (with better performance or instrumentation).

New in version 3.5.2.

loop.create_task(*coro*, *, *name*=*None*, *context*=*None*)

Schedule the execution of coroutine *coro*. Return a **Task** object.

Third-party event loops can use their own subclass of **Task** for interoperability. In this case, the result type is a subclass of **Task**.

If the *name* argument is provided and not `None`, it is set as the name of the task using **Task.set_name()**.

An optional keyword-only *context* argument allows specifying a custom **contextvars.Context** for the *coro* to run in. The current context copy is created when no *context* is provided.

Changed in version 3.8: Added the *name* parameter.

Changed in version 3.11: Added the *context* parameter.

loop.set_task_factory(*factory*)

Set a task factory that will be used by **loop.create_task()**.

If *factory* is `None` the default task factory will be set. Otherwise, *factory* must be a *callable* with the signature matching `(loop, coro, context=None)`, where *loop* is a reference to the active event loop, and *coro* is a coroutine object. The callable must return a **asyncio.Future**-compatible object.

loop.get_task_factory()

Return a task factory or `None` if the default one is in use.

Opening network connections

coroutine loop.create_connection(*protocol_factory*, *host=None*, *port=None*, ***, *ssl=None*, *family=0*, *proto=0*, *flags=0*, *sock=None*, *local_addr=None*, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *happy_eyeballs_delay=None*, *interleave=None*)

Open a streaming transport connection to a given address specified by *host* and *port*.

The socket family can be either **`AF_INET`** or **`AF_INET6`** depending on *host* (or the *family* argument, if provided).

The socket type will be **`SOCK_STREAM`**.

protocol_factory must be a callable returning an asyncio protocol implementation.

This method will try to establish the connection in the background. When successful, it returns a `(transport, protocol)` pair.

The chronological synopsis of the underlying operation is as follows:

1. The connection is established and a transport is created for it.
2. *protocol_factory* is called without arguments and is expected to return a protocol instance.
3. The protocol instance is coupled with the transport by calling its **`connection_made()`** method.
4. A `(transport, protocol)` tuple is returned on success.

The created transport is an implementation-dependent bidirectional stream.

Other arguments:

- *ssl*: if given and not false, a SSL/TLS transport is created (by default a plain TCP transport is created). If *ssl* is a **`ssl.SSLContext`** object, this context is used to create the transport; if *ssl* is **`True`**, a default context returned from **`ssl.create_default_context()`** is used.

  See also

  SSL/TLS security considerations

- *server_hostname* sets or overrides the hostname that the target server's certificate will be matched against. Should only be passed if *ssl* is not `None`. By default the value of the *host* argument is used. If *host* is empty, there is no default and you must pass a value for *server_hostname*. If *server_hostname* is an empty string, hostname matching is disabled (which is a serious security risk, allowing for potential man-in-the-middle attacks).

- *family*, *proto*, *flags* are the optional address family, protocol and flags to be passed through to getaddrinfo() for *host* resolution. If given, these should all be integers from the corresponding **`socket`** module constants.

- *happy_eyeballs_delay*, if given, enables Happy Eyeballs for this connection. It should be a floating-point number representing the amount of time in seconds to wait for a connection attempt to complete, before starting the next attempt in parallel. This is the "Connection Attempt Delay" as defined in **RFC 8305** [https://datatracker.ietf.org/doc/html/rfc8305.html]. A sensible default value recommended by the RFC is `0.25` (250 milliseconds).

- *interleave* controls address reordering when a host name resolves to multiple IP addresses. If `0` or unspecified, no reordering is done, and addresses are tried in the order returned by **`getaddrinfo()`**. If a positive

integer is specified, the addresses are interleaved by address family, and the given integer is interpreted as "First Address Family Count" as defined in **RFC 8305** [https://datatracker.ietf.org/doc/html/rfc8305.html]. The default is `0` if *happy_eyeballs_delay* is not specified, and `1` if it is.

- *sock*, if given, should be an existing, already connected **`socket.socket`** object to be used by the transport. If *sock* is given, none of *host*, *port*, *family*, *proto*, *flags*, *happy_eyeballs_delay*, *interleave* and *local_addr* should be specified.

  Note

  The *sock* argument transfers ownership of the socket to the transport created. To close the socket, call the transport's **`close()`** method.

- *local_addr*, if given, is a `(local_host, local_port)` tuple used to bind the socket locally. The *local_host* and *local_port* are looked up using `getaddrinfo()`, similarly to *host* and *port*.

- *ssl_handshake_timeout* is (for a TLS connection) the time in seconds to wait for the TLS handshake to complete before aborting the connection. `60.0` seconds if `None` (default).

- *ssl_shutdown_timeout* is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).

Changed in version 3.5: Added support for SSL/TLS in **`ProactorEventLoop`**.

Changed in version 3.6: The socket option **`TCP_NODELAY`** is set by default for all TCP connections.

Changed in version 3.7: Added the *ssl_handshake_timeout* parameter.

Changed in version 3.8: Added the *happy_eyeballs_delay* and *interleave* parameters.

Happy Eyeballs Algorithm: Success with Dual-Stack Hosts. When a server's IPv4 path and protocol are working, but the server's IPv6 path and protocol are not working, a dual-stack client application experiences significant connection delay compared to an IPv4-only client. This is undesirable because it causes the dual- stack client to have a worse user experience. This document specifies requirements for algorithms that reduce this user-visible delay and provides an algorithm.

For more information: https://tools.ietf.org/html/rfc6555

Changed in version 3.11: Added the *ssl_shutdown_timeout* parameter.

See also

The **`open_connection()`** function is a high-level alternative API. It returns a pair of (**`StreamReader`**, **`StreamWriter`**) that can be used directly in async/await code.

coroutine loop.create_datagram_endpoint(*protocol_factory*, *local_addr=None*, *remote_addr=None*, ***, *family=0*, *proto=0*, *flags=0*, *reuse_port=None*, *allow_broadcast=None*, *sock=None*)

Create a datagram connection.

The socket family can be either **`AF_INET`**, **`AF_INET6`**, or **`AF_UNIX`**, depending on *host* (or the *family* argument, if provided).

The socket type will be **`SOCK_DGRAM`**.

protocol_factory must be a callable returning a protocol implementation.

A tuple of `(transport, protocol)` is returned on success.

Other arguments:

- *local_addr*, if given, is a `(local_host, local_port)` tuple used to bind the socket locally. The *local_host* and *local_port* are looked up using **`getaddrinfo()`**.
- *remote_addr*, if given, is a `(remote_host, remote_port)` tuple used to connect the socket to a remote address. The *remote_host* and *remote_port* are looked up using **`getaddrinfo()`**.
- *family*, *proto*, *flags* are the optional address family, protocol and flags to be passed through to **`getaddrinfo()`** for *host* resolution. If given, these should all be integers from the corresponding **`socket`** module constants.
- *reuse_port* tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows and some Unixes. If the **`SO_REUSEPORT`** constant is not defined then this capability is unsupported.
- *allow_broadcast* tells the kernel to allow this endpoint to send messages to the broadcast address.
- *sock* can optionally be specified in order to use a preexisting, already connected, **`socket.socket`** object to be used by the transport. If specified, *local_addr* and *remote_addr* should be omitted (must be **`None`**).

  Note

  The *sock* argument transfers ownership of the socket to the transport created. To close the socket, call the

transport's **close()** method.

See UDP echo client protocol and UDP echo server protocol examples.

Changed in version 3.4.4: The *family*, *proto*, *flags*, *reuse_address*, *reuse_port*, *allow_broadcast*, and *sock* parameters were added.

Changed in version 3.8.1: The *reuse_address* parameter is no longer supported, as using **SO_REUSEADDR** poses a significant security concern for UDP. Explicitly passing `reuse_address=True` will raise an exception.

When multiple processes with differing UIDs assign sockets to an identical UDP socket address with `SO_REUSEADDR`, incoming packets can become randomly distributed among the sockets.

For supported platforms, *reuse_port* can be used as a replacement for similar functionality. With *reuse_port*, **SO_REUSEPORT** is used instead, which specifically prevents processes with differing UIDs from assigning sockets to the same socket address.

Changed in version 3.8: Added support for Windows.

Changed in version 3.11: The *reuse_address* parameter, disabled since Python 3.9.0, 3.8.1, 3.7.6 and 3.6.10, has been entirely removed.

coroutine loop.create_unix_connection(*protocol_factory*, *path=None*, ***, *ssl=None*, *sock=None*, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*)

Create a Unix connection.

The socket family will be **AF_UNIX**; socket type will be **SOCK_STREAM**.

A tuple of `(transport, protocol)` is returned on

success.

path is the name of a Unix domain socket and is required, unless a *sock* parameter is specified. Abstract Unix sockets, `str`, `bytes`, and `Path` paths are supported.

See the documentation of the `loop.create_connection()` method for information about arguments to this method.

Availability: Unix.

Changed in version 3.7: Added the *ssl_handshake_timeout* parameter. The *path* parameter can now be a path-like object.

Changed in version 3.11: Added the *ssl_shutdown_timeout* parameter.

Creating network servers

coroutine loop.create_server(*protocol_factory*, *host=None*, *port=None*, ***, *family=socket.AF_UNSPEC*, *flags=socket.AI_PASSIVE*, *sock=None*, *backlog=100*, *ssl=None*, *reuse_address=None*, *reuse_port=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *start_serving=True*)

Create a TCP server (socket type `SOCK_STREAM`) listening on *port* of the *host* address.

Returns a `Server` object.

Arguments:

- *protocol_factory* must be a callable returning a protocol implementation.
- The *host* parameter can be set to several types which determine where the server would be listening:
  - If *host* is a string, the TCP server is bound to a single network interface specified by *host*.
  - If *host* is a sequence of strings, the TCP server is

bound to all network interfaces specified by the sequence.
    - If *host* is an empty string or `None`, all interfaces are assumed and a list of multiple sockets will be returned (most likely one for IPv4 and another one for IPv6).

- The *port* parameter can be set to specify which port the server should listen on. If `0` or `None` (the default), a random unused port will be selected (note that if *host* resolves to multiple network interfaces, a different random port will be selected for each interface).

- *family* can be set to either **`socket.AF_INET`** or **`AF_INET6`** to force the socket to use IPv4 or IPv6. If not set, the *family* will be determined from host name (defaults to **`AF_UNSPEC`**).

- *flags* is a bitmask for **`getaddrinfo()`**.

- *sock* can optionally be specified in order to use a preexisting socket object. If specified, *host* and *port* must not be specified.

  Note

  The *sock* argument transfers ownership of the socket to the server created. To close the socket, call the server's **`close()`** method.

- *backlog* is the maximum number of queued connections passed to **`listen()`** (defaults to 100).

- *ssl* can be set to an **`SSLContext`** instance to enable TLS over the accepted connections.

- *reuse_address* tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire. If not specified will automatically be set to `True` on Unix.

- *reuse_port* tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows.

- *ssl_handshake_timeout* is (for a TLS server) the time in seconds to wait for the TLS handshake to complete before aborting the connection. `60.0` seconds if `None` (default).

- *ssl_shutdown_timeout* is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).

- *start_serving* set to `True` (the default) causes the created server to start accepting connections immediately. When set to `False`, the user should await on **`Server.start_serving()`** or **`Server.serve_forever()`** to make the server to start accepting connections.

Changed in version 3.5: Added support for SSL/TLS in **`ProactorEventLoop`**.

Changed in version 3.5.1: The *host* parameter can be a sequence of strings.

Changed in version 3.6: Added *ssl_handshake_timeout* and *start_serving* parameters. The socket option **`TCP_NODELAY`** is set by default for all TCP connections.

Changed in version 3.11: Added the *ssl_shutdown_timeout* parameter.

See also

The **`start_server()`** function is a higher-level alternative API that returns a pair of **`StreamReader`** and **`StreamWriter`** that can be used in an async/await code.

coroutine loop.create_unix_server(*protocol_factory*, *path=None*, ***, *sock=None*, *backlog=100*, *ssl=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*, *start_serving=True*)

Similar to `loop.create_server()` but works with the `AF_UNIX` socket family.

path is the name of a Unix domain socket, and is required, unless a *sock* argument is provided. Abstract Unix sockets, `str`, `bytes`, and `Path` paths are supported.

See the documentation of the `loop.create_server()` method for information about arguments to this method.

Availability: Unix.

Changed in version 3.7: Added the *ssl_handshake_timeout* and *start_serving* parameters. The *path* parameter can now be a `Path` object.

Changed in version 3.11: Added the *ssl_shutdown_timeout* parameter.

coroutine loop.connect_accepted_socket(*protocol_factory*, *sock*, ***, *ssl=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*)

Wrap an already accepted connection into a transport/protocol pair.

This method can be used by servers that accept connections outside of asyncio but that use asyncio to handle them.

Parameters:

- *protocol_factory* must be a callable returning a protocol implementation.
- *sock* is a preexisting socket object returned from `socket.accept`.

Note

The *sock* argument transfers ownership of the socket to the transport created. To close the socket, call the transport's `close()` method.

- *ssl* can be set to an `SSLContext` to enable SSL over the accepted connections.
- *ssl_handshake_timeout* is (for an SSL connection) the time in seconds to wait for the SSL handshake to complete before aborting the connection. `60.0` seconds if `None` (default).
- *ssl_shutdown_timeout* is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).

Returns a `(transport, protocol)` pair.

New in version 3.5.3.

Changed in version 3.7: Added the *ssl_handshake_timeout* parameter.

Changed in version 3.11: Added the *ssl_shutdown_timeout* parameter.

Transferring files

coroutine loop.sendfile(*transport*, *file*, *offset=0*, *count=None*, *, *fallback=True*)

Send a *file* over a *transport*. Return the total number of bytes sent.

The method uses high-performance `os.sendfile()` if available.

file must be a regular file object opened in binary mode.

offset tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to

sending the file until EOF is reached. File position is always updated, even when this method raises an error, and **`file.tell()`** can be used to obtain the actual number of bytes sent.

fallback set to `True` makes asyncio to manually read and send the file when the platform does not support the sendfile system call (e.g. Windows or SSL socket on Unix).

Raise **`SendfileNotAvailableError`** if the system does not support the *sendfile* syscall and *fallback* is `False`.

New in version 3.7.

TLS Upgrade

coroutine loop.start_tls(*transport*, *protocol*, *sslcontext*, *, *server_side=False*, *server_hostname=None*, *ssl_handshake_timeout=None*, *ssl_shutdown_timeout=None*)

Upgrade an existing transport-based connection to TLS.

Create a TLS coder/decoder instance and insert it between the *transport* and the *protocol*. The coder/decoder implements both *transport*-facing protocol and *protocol*-facing transport.

Return the created two-interface instance. After *await*, the *protocol* must stop using the original *transport* and communicate with the returned object only because the coder caches *protocol*-side data and sporadically exchanges extra TLS session packets with *transport*.

Parameters:

- *transport* and *protocol* instances that methods like **`create_server()`** and **`create_connection()`** return.
- *sslcontext*: a configured instance of **`SSLContext`**.
- *server_side* pass `True` when a server-side connection is being upgraded (like the one created by **`create_server()`**).

- *server_hostname*: sets or overrides the host name that the target server's certificate will be matched against.
- *ssl_handshake_timeout* is (for a TLS connection) the time in seconds to wait for the TLS handshake to complete before aborting the connection. `60.0` seconds if `None` (default).
- *ssl_shutdown_timeout* is the time in seconds to wait for the SSL shutdown to complete before aborting the connection. `30.0` seconds if `None` (default).

New in version 3.7.

Changed in version 3.11: Added the *ssl_shutdown_timeout* parameter.

Watching file descriptors

loop.add_reader(*fd*, *callback*, **args*)

Start monitoring the *fd* file descriptor for read availability and invoke *callback* with the specified arguments once *fd* is available for reading.

loop.remove_reader(*fd*)

Stop monitoring the *fd* file descriptor for read availability.

loop.add_writer(*fd*, *callback*, **args*)

Start monitoring the *fd* file descriptor for write availability and invoke *callback* with the specified arguments once *fd* is available for writing.

Use **`functools.partial()`** to pass keyword arguments to *callback*.

loop.remove_writer(*fd*)

Stop monitoring the *fd* file descriptor for write availability.

See also Platform Support section for some limitations of these methods.

Working with socket objects directly

In general, protocol implementations that use transport-based APIs such as `loop.create_connection()` and `loop.create_server()` are faster than implementations that work with sockets directly. However, there are some use cases when performance is not critical, and working with `socket` objects directly is more convenient.

coroutine loop.sock_recv(*sock*, *nbytes*)

Receive up to *nbytes* from *sock*. Asynchronous version of `socket.recv()`.

Return the received data as a bytes object.

sock must be a non-blocking socket.

Changed in version 3.7: Even though this method was always documented as a coroutine method, releases before Python 3.7 returned a `Future`. Since Python 3.7 this is an `async def` method.

coroutine loop.sock_recv_into(*sock*, *buf*)

Receive data from *sock* into the *buf* buffer. Modeled after the blocking `socket.recv_into()` method.

Return the number of bytes written to the buffer.

sock must be a non-blocking socket.

New in version 3.7.

coroutine loop.sock_recvfrom(*sock*, *bufsize*)

Receive a datagram of up to *bufsize* from *sock*. Asynchronous version of `socket.recvfrom()`.

Return a tuple of (received data, remote address).

sock must be a non-blocking socket.

New in version 3.11.

coroutine loop.sock_recvfrom_into(*sock*, *buf*, *nbytes=0*)

Receive a datagram of up to *nbytes* from *sock* into *buf*. Asynchronous version of `socket.recvfrom_into()`.

Return a tuple of (number of bytes received, remote address).

sock must be a non-blocking socket.

New in version 3.11.

coroutine loop.sock_sendall(*sock*, *data*)

Send *data* to the *sock* socket. Asynchronous version of `socket.sendall()`.

This method continues to send to the socket until either all data in *data* has been sent or an error occurs. `None` is returned on success. On error, an exception is raised. Additionally, there is no way to determine how much data, if any, was successfully processed by the receiving end of the connection.

sock must be a non-blocking socket.

Changed in version 3.7: Even though the method was always documented as a coroutine method, before Python 3.7 it returned a `Future`. Since Python 3.7, this is an `async def` method.

coroutine loop.sock_sendto(*sock*, *data*, *address*)

Send a datagram from *sock* to *address*. Asynchronous version of `socket.sendto()`.

Return the number of bytes sent.

sock must be a non-blocking socket.

New in version 3.11.

coroutine loop.sock_connect(*sock*, *address*)

Connect *sock* to a remote socket at *address*.

Asynchronous version of `socket.connect()`.

sock must be a non-blocking socket.

Changed in version 3.5.2: `address` no longer needs to be resolved. `sock_connect` will try to check if the *address* is already resolved by calling `socket.inet_pton()`. If not, `loop.getaddrinfo()` will be used to resolve the *address*.

See also

`loop.create_connection()` and `asyncio.open_connection()`.

coroutine loop.sock_accept(*sock*)

Accept a connection. Modeled after the blocking `socket.accept()` method.

The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

sock must be a non-blocking socket.

Changed in version 3.7: Even though the method was always documented as a coroutine method, before Python 3.7 it returned a `Future`. Since Python 3.7, this is an `async def` method.

See also

`loop.create_server()` and `start_server()`.

coroutine loop.sock_sendfile(*sock*, *file*, *offset=0*, *count=None*, ***, *fallback=True*)

Send a file using high-performance **os.sendfile** if possible. Return the total number of bytes sent.

Asynchronous version of **socket.sendfile()**.

sock must be a non-blocking **socket.SOCK_STREAM socket**.

file must be a regular file object open in binary mode.

offset tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is always updated, even when this method raises an error, and **file.tell()** can be used to obtain the actual number of bytes sent.

fallback, when set to `True`, makes asyncio manually read and send the file when the platform does not support the sendfile syscall (e.g. Windows or SSL socket on Unix).

Raise **SendfileNotAvailableError** if the system does not support *sendfile* syscall and *fallback* is `False`.

sock must be a non-blocking socket.

New in version 3.7.

DNS

coroutine loop.getaddrinfo(*host*, *port*, ***, *family=0*, *type=0*, *proto=0*, *flags=0*)

Asynchronous version of **socket.getaddrinfo()**.

coroutine loop.getnameinfo(*sockaddr*, *flags=0*)

Asynchronous version of **socket.getnameinfo()**.

Changed in version 3.7: Both *getaddrinfo* and *getnameinfo* methods were always documented to return a coroutine, but prior to Python 3.7 they were, in fact, returning **`asyncio.Future`** objects. Starting with Python 3.7 both methods are coroutines.

Working with pipes

coroutine loop.connect_read_pipe(*protocol_factory*, *pipe*)

Register the read end of *pipe* in the event loop.

protocol_factory must be a callable returning an asyncio protocol implementation.

pipe is a file-like object.

Return pair `(transport, protocol)`, where *transport* supports the **`ReadTransport`** interface and *protocol* is an object instantiated by the *protocol_factory*.

With **`SelectorEventLoop`** event loop, the *pipe* is set to non-blocking mode.

coroutine loop.connect_write_pipe(*protocol_factory*, *pipe*)

Register the write end of *pipe* in the event loop.

protocol_factory must be a callable returning an asyncio protocol implementation.

pipe is file-like object.

Return pair `(transport, protocol)`, where *transport* supports **`WriteTransport`** interface and *protocol* is an object instantiated by the *protocol_factory*.

With **`SelectorEventLoop`** event loop, the *pipe* is set to non-blocking mode.

Note

`SelectorEventLoop` does not support the above methods on

Windows. Use **`ProactorEventLoop`** instead for Windows.

See also

The **`loop.subprocess_exec()`** and **`loop.subprocess_shell()`** methods.

Unix signals

loop.add_signal_handler(*signum*, *callback*, **args*)

Set *callback* as the handler for the *signum* signal.

The callback will be invoked by *loop*, along with other queued callbacks and runnable coroutines of that event loop. Unlike signal handlers registered using **`signal.signal()`**, a callback registered with this function is allowed to interact with the event loop.

Raise **`ValueError`** if the signal number is invalid or uncatchable. Raise **`RuntimeError`** if there is a problem setting up the handler.

Use **`functools.partial()`** to pass keyword arguments to *callback*.

Like **`signal.signal()`**, this function must be invoked in the main thread.

loop.remove_signal_handler(*sig*)

Remove the handler for the *sig* signal.

Return `True` if the signal handler was removed, or `False` if no handler was set for the given signal.

Availability: Unix.

See also

The **signal** module.

Executing code in thread or process pools

awaitable loop.run_in_executor(*executor*, *func*, **args*)

Arrange for *func* to be called in the specified executor.

The *executor* argument should be an **concurrent.futures.Executor** instance. The default executor is used if *executor* is `None`.

Example:

```
import asyncio
import concurrent.futures

def blocking_io():
    # File operations (such as logging) can block t
    # event loop: run them in a thread pool.
    with open('/dev/urandom', 'rb') as f:
        return f.read(100)

def cpu_bound():
    # CPU-bound operations will block the event loo
    # in general it is preferable to run them in a
    # process pool.
    return sum(i * i for i in range(10 ** 7))

async def main():
    loop = asyncio.get_running_loop()

    ## Options:

    # 1. Run in the default loop's executor:
    result = await loop.run_in_executor(
        None, blocking_io)
    print('default thread pool', result)
```

```
        # 2. Run in a custom thread pool:
        with concurrent.futures.ThreadPoolExecutor() as
            result = await loop.run_in_executor(
                pool, blocking_io)
            print('custom thread pool', result)

        # 3. Run in a custom process pool:
        with concurrent.futures.ProcessPoolExecutor() a
            result = await loop.run_in_executor(
                pool, cpu_bound)
            print('custom process pool', result)

if __name__ == '__main__':
    asyncio.run(main())
```

Note that the entry point guard (`if __name__ == '__main__'`) is required for option 3 due to the peculiarities of **`multiprocessing`**, which is used by **`ProcessPoolExecutor`**. See Safe importing of main module.

This method returns a **`asyncio.Future`** object.

Use **`functools.partial()`** to pass keyword arguments to *func*.

Changed in version 3.5.3: **`loop.run_in_executor()`** no longer configures the `max_workers` of the thread pool executor it creates, instead leaving it up to the thread pool executor (**`ThreadPoolExecutor`**) to set the default.

loop.set_default_executor(*executor*)

Set *executor* as the default executor used by **`run_in_executor()`**. *executor* must be an instance of **`ThreadPoolExecutor`**.

Changed in version 3.11: executor must be an instance of **`ThreadPoolExecutor`**.

Error Handling API

Allows customizing how exceptions are handled in the event loop.

loop.set_exception_handler(*handler*)

Set *handler* as the new event loop exception handler.

If *handler* is `None`, the default exception handler will be set. Otherwise, *handler* must be a callable with the signature matching `(loop, context)`, where `loop` is a reference to the active event loop, and `context` is a `dict` object containing the details of the exception (see **`call_exception_handler()`** documentation for details about context).

loop.get_exception_handler()

Return the current exception handler, or `None` if no custom exception handler was set.

New in version 3.5.2.

loop.default_exception_handler(*context*)

Default exception handler.

This is called when an exception occurs and no exception handler is set. This can be called by a custom exception handler that wants to defer to the default handler behavior.

context parameter has the same meaning as in **`call_exception_handler()`**.

loop.call_exception_handler(*context*)

Call the current event loop exception handler.

context is a `dict` object containing the following keys (new keys may be introduced in future Python versions):

- 'message': Error message;
- 'exception' (optional): Exception object;

- ‘future’ (optional): **asyncio.Future** instance;
- ‘task’ (optional): **asyncio.Task** instance;
- ‘handle’ (optional): **asyncio.Handle** instance;
- ‘protocol’ (optional): Protocol instance;
- ‘transport’ (optional): Transport instance;
- ‘socket’ (optional): **socket.socket** instance;

- ‘asyncgen’ (optional): Asynchronous generator that caused
  the exception.

Note

This method should not be overloaded in subclassed event loops. For custom exception handling, use the **set_exception_handler()** method.

Enabling debug mode

loop.get_debug()

Get the debug mode (**bool**) of the event loop.

The default value is `True` if the environment variable **PYTHONASYNCIODEBUG** is set to a non-empty string, `False` otherwise.

loop.set_debug(*enabled: bool*)

Set the debug mode of the event loop.

Changed in version 3.7: The new Python Development Mode can now also be used to enable the debug mode.

See also

The debug mode of asyncio.

Running Subprocesses

Methods described in this subsections are low-level. In regular async/await code consider using the high-level **`asyncio.create_subprocess_shell()`** and **`asyncio.create_subprocess_exec()`** convenience functions instead.

Note

On Windows, the default event loop **`ProactorEventLoop`** supports subprocesses, whereas **`SelectorEventLoop`** does not. See Subprocess Support on Windows for details.

coroutine loop.subprocess_exec(*protocol_factory*, **args*, *stdin=subprocess.PIPE*, *stdout=subprocess.PIPE*, *stderr=subprocess.PIPE*, ***kwargs*)

Create a subprocess from one or more string arguments specified by *args*.

args must be a list of strings represented by:

- **`str`**;
- or **`bytes`**, encoded to the filesystem encoding.

The first string specifies the program executable, and the remaining strings specify the arguments. Together, string arguments form the `argv` of the program.

This is similar to the standard library **`subprocess.Popen`** class called with `shell=False` and the list of strings passed as the first argument; however, where **`Popen`** takes a single argument which is list of strings, *subprocess_exec* takes multiple string arguments.

The *protocol_factory* must be a callable returning a subclass of the **`asyncio.SubprocessProtocol`** class.

Other parameters:

- *stdin* can be any of these:

    - a file-like object representing a pipe to be connected to the subprocess's standard input stream using **`connect_write_pipe()`**
    - the **`subprocess.PIPE`** constant (default) which will create a new pipe and connect it,
    - the value `None` which will make the subprocess inherit the file descriptor from this process
    - the **`subprocess.DEVNULL`** constant which indicates that the special **`os.devnull`** file will be used

- *stdout* can be any of these:

    - a file-like object representing a pipe to be connected to the subprocess's standard output stream using **`connect_write_pipe()`**
    - the **`subprocess.PIPE`** constant (default) which will create a new pipe and connect it,
    - the value `None` which will make the subprocess inherit the file descriptor from this process
    - the **`subprocess.DEVNULL`** constant which indicates that the special **`os.devnull`** file will be used

- *stderr* can be any of these:

    - a file-like object representing a pipe to be connected to the subprocess's standard error stream using **`connect_write_pipe()`**
    - the **`subprocess.PIPE`** constant (default) which will create a new pipe and connect it,
    - the value `None` which will make the subprocess inherit the file descriptor from this process
    - the **`subprocess.DEVNULL`** constant which indicates that the special **`os.devnull`** file will be used
    - the **`subprocess.STDOUT`** constant which will connect the standard error stream to the process' standard output stream

- All other keyword arguments are passed to

subprocess.Popen without interpretation, except for *bufsize*, *universal_newlines*, *shell*, *text*, *encoding* and *errors*, which should not be specified at all.

The `asyncio` subprocess API does not support decoding the streams as text. **bytes.decode()** can be used to convert the bytes returned from the stream to text.

See the constructor of the **subprocess.Popen** class for documentation on other arguments.

Returns a pair of `(transport, protocol)`, where *transport* conforms to the **asyncio.SubprocessTransport** base class and *protocol* is an object instantiated by the *protocol_factory*.

coroutine loop.subprocess_shell(*protocol_factory*, *cmd*, *, *stdin=subprocess.PIPE*, *stdout=subprocess.PIPE*, *stderr=subprocess.PIPE*, ***kwargs*)

Create a subprocess from *cmd*, which can be a **str** or a **bytes** string encoded to the filesystem encoding, using the platform's "shell" syntax.

This is similar to the standard library **subprocess.Popen** class called with `shell=True`.

The *protocol_factory* must be a callable returning a subclass of the **SubprocessProtocol** class.

See **subprocess_exec()** for more details about the remaining arguments.

Returns a pair of `(transport, protocol)`, where *transport* conforms to the **SubprocessTransport** base class and *protocol* is an object instantiated by the *protocol_factory*.

Note

It is the application's responsibility to ensure that all whitespace

and special characters are quoted appropriately to avoid shell injection [https://en.wikipedia.org/wiki/Shell_injection#Shell_injection] vulnerabilities. The **`shlex.quote()`** function can be used to properly escape whitespace and special characters in strings that are going to be used to construct shell commands.

Callback Handles

class asyncio.Handle

A callback wrapper object returned by **`loop.call_soon()`**, **`loop.call_soon_threadsafe()`**.

cancel()

Cancel the callback. If the callback has already been canceled or executed, this method has no effect.

cancelled()

Return `True` if the callback was cancelled.

New in version 3.7.

class asyncio.TimerHandle

A callback wrapper object returned by **`loop.call_later()`**, and **`loop.call_at()`**.

This class is a subclass of **`Handle`**.

when()

Return a scheduled callback time as **`float`** seconds.

The time is an absolute timestamp, using the same time reference as **`loop.time()`**.

New in version 3.7.

Server Objects

Server objects are created by **loop.create_server()**, **loop.create_unix_server()**, **start_server()**, and **start_unix_server()** functions.

Do not instantiate the class directly.

class asyncio.Server

Server objects are asynchronous context managers. When used in an `async with` statement, it's guaranteed that the Server object is closed and not accepting new connections when the `async with` statement is completed:

```
srv = await loop.create_server(...)

async with srv:
    # some code

# At this point, srv is closed and no longer accept
```

Changed in version 3.7: Server object is an asynchronous context manager since Python 3.7.

close()

Stop serving: close listening sockets and set the **sockets** attribute to `None`.

The sockets that represent existing incoming client connections are left open.

The server is closed asynchronously, use the **wait_closed()** coroutine to wait until the server is closed.

get_loop()

Return the event loop associated with the server object.

New in version 3.7.

coroutine start_serving()

Start accepting connections.

This method is idempotent, so it can be called when the server is already serving.

The *start_serving* keyword-only parameter to **`loop.create_server()`** and **`asyncio.start_server()`** allows creating a Server object that is not accepting connections initially. In this case `Server.start_serving()`, or **`Server.serve_forever()`** can be used to make the Server start accepting connections.

New in version 3.7.

coroutine serve_forever()

Start accepting connections until the coroutine is cancelled. Cancellation of `serve_forever` task causes the server to be closed.

This method can be called if the server is already accepting connections. Only one `serve_forever` task can exist per one *Server* object.

Example:

```
async def client_connected(reader, writer):
    # Communicate with the client with
    # reader/writer streams.  For example:
    await reader.readline()

async def main(host, port):
    srv = await asyncio.start_server(
        client_connected, host, port)
    await srv.serve_forever()

asyncio.run(main('127.0.0.1', 0))
```

New in version 3.7.

is_serving()

Return `True` if the server is accepting new connections.

New in version 3.7.

coroutine wait_closed()

Wait until the **`close()`** method completes.

sockets

List of **`socket.socket`** objects the server is listening on.

Changed in version 3.7: Prior to Python 3.7 `Server.sockets` used to return an internal list of server sockets directly. In 3.7 a copy of that list is returned.

Event Loop Implementations

asyncio ships with two different event loop implementations: **`SelectorEventLoop`** and **`ProactorEventLoop`**.

By default asyncio is configured to use **`SelectorEventLoop`** on Unix and **`ProactorEventLoop`** on Windows.

class asyncio.SelectorEventLoop

An event loop based on the **`selectors`** module.

Uses the most efficient *selector* available for the given platform. It is also possible to manually configure the exact selector implementation to be used:

```
import asyncio
import selectors

class MyPolicy(asyncio.DefaultEventLoopPolicy):
   def new_event_loop(self):
```

```
            selector = selectors.SelectSelector()
            return asyncio.SelectorEventLoop(selector)

    asyncio.set_event_loop_policy(MyPolicy())
```

Availability: Unix, Windows.

class asyncio.ProactorEventLoop

An event loop for Windows that uses “I/O Completion Ports” (IOCP).

Availability: Windows.

See also

MSDN documentation on I/O Completion Ports [https://docs.microsoft.com/en-ca/windows/desktop/FileIO/i-o-completion-ports].

class asyncio.AbstractEventLoop

Abstract base class for asyncio-compliant event loops.

The Event Loop Methods section lists all methods that an alternative implementation of `AbstractEventLoop` should have defined.

Examples

Note that all examples in this section **purposefully** show how to use the low-level event loop APIs, such as **`loop.run_forever()`** and **`loop.call_soon()`**. Modern asyncio applications rarely need to be written this way; consider using the high-level functions like **`asyncio.run()`**.

Hello World with call_soon()

An example using the **`loop.call_soon()`** method to schedule a callback. The callback displays `"Hello World"` and then stops

the event loop:

```
import asyncio

def hello_world(loop):
    """A callback to print 'Hello World' and stop the ev
    print('Hello World')
    loop.stop()

loop = asyncio.new_event_loop()

# Schedule a call to hello_world()
loop.call_soon(hello_world, loop)

# Blocking call interrupted by loop.stop()
try:
    loop.run_forever()
finally:
    loop.close()
```

See also

A similar Hello World example created with a coroutine and the **`run()`** function.

Display the current date with call_later()

An example of a callback displaying the current date every second. The callback uses the **`loop.call_later()`** method to reschedule itself after 5 seconds, and then stops the event loop:

```
import asyncio
import datetime

def display_date(end_time, loop):
    print(datetime.datetime.now())
    if (loop.time() + 1.0) < end_time:
        loop.call_later(1, display_date, end_time, loop)
```

```
    else:
        loop.stop()

loop = asyncio.new_event_loop()

# Schedule the first call to display_date()
end_time = loop.time() + 5.0
loop.call_soon(display_date, end_time, loop)

# Blocking call interrupted by loop.stop()
try:
    loop.run_forever()
finally:
    loop.close()
```

See also

A similar current date example created with a coroutine and the **`run()`** function.

Watch a file descriptor for read events

Wait until a file descriptor received some data using the **`loop.add_reader()`** method and then close the event loop:

```
import asyncio
from socket import socketpair

# Create a pair of connected file descriptors
rsock, wsock = socketpair()

loop = asyncio.new_event_loop()

def reader():
    data = rsock.recv(100)
    print("Received:", data.decode())

    # We are done: unregister the file descriptor
```

```
    loop.remove_reader(rsock)

    # Stop the event loop
    loop.stop()

# Register the file descriptor for read event
loop.add_reader(rsock, reader)

# Simulate the reception of data from the network
loop.call_soon(wsock.send, 'abc'.encode())

try:
    # Run the event loop
    loop.run_forever()
finally:
    # We are done. Close sockets and the event loop.
    rsock.close()
    wsock.close()
    loop.close()
```

See also

- A similar example using transports, protocols, and the **`loop.create_connection()`** method.
- Another similar example using the high-level **`asyncio.open_connection()`** function and streams.

Set signal handlers for SIGINT and SIGTERM

(This `signals` example only works on Unix.)

Register handlers for signals **`SIGINT`** and **`SIGTERM`** using the **`loop.add_signal_handler()`** method:

```
import asyncio
import functools
import os
import signal
```

```
def ask_exit(signame, loop):
    print("got signal %s: exit" % signame)
    loop.stop()

async def main():
    loop = asyncio.get_running_loop()

    for signame in {'SIGINT', 'SIGTERM'}:
        loop.add_signal_handler(
            getattr(signal, signame),
            functools.partial(ask_exit, signame, loop))

    await asyncio.sleep(3600)

print("Event loop running for 1 hour, press Ctrl+C to ir
print(f"pid {os.getpid()}: send SIGINT or SIGTERM to exi

asyncio.run(main())
```

Futures

Source code: Lib/asyncio/futures.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/futures.py], Lib/asyncio/base_futures.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/base_futures.py]

Future objects are used to bridge **low-level callback-based code** with high-level async/await code.

Future Functions

asyncio.isfuture(*obj*)

Return `True` if *obj* is either of:

- an instance of **`asyncio.Future`**,
- an instance of **`asyncio.Task`**,
- a Future-like object with a `_asyncio_future_blocking` attribute.

New in version 3.5.

asyncio.ensure_future(*obj*, *, *loop=None*)

Return:

- *obj* argument as is, if *obj* is a **`Future`**, a **`Task`**, or a Future-like object (**`isfuture()`** is used for the test.)
- a **`Task`** object wrapping *obj*, if *obj* is a coroutine (**`iscoroutine()`** is used for the test); in this case the coroutine will be scheduled by `ensure_future()`.
- a **`Task`** object that would await on *obj*, if *obj* is an awaitable (**`inspect.isawaitable()`** is used for the test.)

If *obj* is neither of the above a **`TypeError`** is raised.

Important

See also the `create_task()` function which is the preferred way for creating new Tasks.

Save a reference to the result of this function, to avoid a task disappearing mid-execution.

Changed in version 3.5.1: The function accepts any awaitable object.

Deprecated since version 3.10: Deprecation warning is emitted if *obj* is not a Future-like object and *loop* is not specified and there is no running event loop.

asyncio.wrap_future(*future*, ***, *loop=None*)

Wrap a `concurrent.futures.Future` object in a `asyncio.Future` object.

Deprecated since version 3.10: Deprecation warning is emitted if *future* is not a Future-like object and *loop* is not specified and there is no running event loop.

Future Object

class asyncio.Future(***, *loop=None*)

A Future represents an eventual result of an asynchronous operation. Not thread-safe.

Future is an awaitable object. Coroutines can await on Future objects until they either have a result or an exception set, or until they are cancelled. A Future can be awaited multiple times and the result is same.

Typically Futures are used to enable low-level callback-based code (e.g. in protocols implemented using asyncio transports) to interoperate with high-level async/await code.

The rule of thumb is to never expose Future objects in user-facing APIs, and the recommended way to create a Future

object is to call `loop.create_future()`. This way alternative event loop implementations can inject their own optimized implementations of a Future object.

Changed in version 3.7: Added support for the `contextvars` module.

Deprecated since version 3.10: Deprecation warning is emitted if *loop* is not specified and there is no running event loop.

result()

Return the result of the Future.

If the Future is *done* and has a result set by the `set_result()` method, the result value is returned.

If the Future is *done* and has an exception set by the `set_exception()` method, this method raises the exception.

If the Future has been *cancelled*, this method raises a `CancelledError` exception.

If the Future's result isn't yet available, this method raises a `InvalidStateError` exception.

set_result(*result*)

Mark the Future as *done* and set its result.

Raises a `InvalidStateError` error if the Future is already *done*.

set_exception(*exception*)

Mark the Future as *done* and set an exception.

Raises a `InvalidStateError` error if the Future is already *done*.

done()

Return `True` if the Future is *done*.

A Future is *done* if it was *cancelled* or if it has a result or an exception set with **`set_result()`** or **`set_exception()`** calls.

cancelled()

Return `True` if the Future was *cancelled*.

The method is usually used to check if a Future is not *cancelled* before setting a result or an exception for it:

```
if not fut.cancelled():
    fut.set_result(42)
```

add_done_callback(*callback*, *, *context*=*None*)

Add a callback to be run when the Future is *done*.

The *callback* is called with the Future object as its only argument.

If the Future is already *done* when this method is called, the callback is scheduled with **`loop.call_soon()`**.

An optional keyword-only *context* argument allows specifying a custom **`contextvars.Context`** for the *callback* to run in. The current context is used when no *context* is provided.

`functools.partial()` can be used to pass parameters to the callback, e.g.:

```
# Call 'print("Future:", fut)' when "fut" is do
fut.add_done_callback(
    functools.partial(print, "Future:"))
```

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** [https://peps.python.org/pep-0567/] for more details.

remove_done_callback(*callback*)

Remove *callback* from the callbacks list.

Returns the number of callbacks removed, which is typically 1, unless a callback was added more than once.

cancel(*msg=None*)

Cancel the Future and schedule callbacks.

If the Future is already *done* or *cancelled*, return `False`. Otherwise, change the Future's state to *cancelled*, schedule the callbacks, and return `True`.

Changed in version 3.9: Added the *msg* parameter.

exception()

Return the exception that was set on this Future.

The exception (or `None` if no exception was set) is returned only if the Future is *done*.

If the Future has been *cancelled*, this method raises a **`CancelledError`** exception.

If the Future isn't *done* yet, this method raises an **`InvalidStateError`** exception.

get_loop()

Return the event loop the Future object is bound to.

New in version 3.7.

This example creates a Future object, creates and schedules an asynchronous Task to set result for the Future, and waits until the Future has a result:

```
async def set_after(fut, delay, value):
    # Sleep for *delay* seconds.
```

```
    await asyncio.sleep(delay)

    # Set *value* as a result of *fut* Future.
    fut.set_result(value)

async def main():
    # Get the current event loop.
    loop = asyncio.get_running_loop()

    # Create a new Future object.
    fut = loop.create_future()

    # Run "set_after()" coroutine in a parallel Task.
    # We are using the low-level "loop.create_task()" AP
    # we already have a reference to the event loop at h
    # Otherwise we could have just used "asyncio.create_
    loop.create_task(
        set_after(fut, 1, '... world'))

    print('hello ...')

    # Wait until *fut* has a result (1 second) and print
    print(await fut)

asyncio.run(main())
```

Important

The Future object was designed to mimic **`concurrent.futures.Future`**. Key differences include:

- unlike asyncio Futures, **`concurrent.futures.Future`** instances cannot be awaited.
- **`asyncio.Future.result()`** and **`asyncio.Future.exception()`** do not accept the *timeout* argument.
- **`asyncio.Future.result()`** and **`asyncio.Future.exception()`** raise an **`InvalidStateError`** exception when the Future is not

done.

- Callbacks registered with **`asyncio.Future.add_done_callback()`** are not called immediately. They are scheduled with **`loop.call_soon()`** instead.
- asyncio Future is not compatible with the **`concurrent.futures.wait()`** and **`concurrent.futures.as_completed()`** functions.
- **`asyncio.Future.cancel()`** accepts an optional `msg` argument, but **`concurrent.futures.cancel()`** does not.

Transports and Protocols

Preface

Transports and Protocols are used by the **low-level** event loop APIs such as `loop.create_connection()`. They use callback-based programming style and enable high-performance implementations of network or IPC protocols (e.g. HTTP).

Essentially, transports and protocols should only be used in libraries and frameworks and never in high-level asyncio applications.

This documentation page covers both Transports and Protocols.

Introduction

At the highest level, the transport is concerned with *how* bytes are transmitted, while the protocol determines *which* bytes to transmit (and to some extent when).

A different way of saying the same thing: a transport is an abstraction for a socket (or similar I/O endpoint) while a protocol is an abstraction for an application, from the transport's point of view.

Yet another view is the transport and protocol interfaces together define an abstract interface for using network I/O and interprocess I/O.

There is always a 1:1 relationship between transport and protocol objects: the protocol calls transport methods to send data, while the transport calls protocol methods to pass it data that has been received.

Most of connection oriented event loop methods (such as `loop.create_connection()`) usually accept a *protocol_factory*

argument used to create a *Protocol* object for an accepted connection, represented by a *Transport* object. Such methods usually return a tuple of `(transport, protocol)`.

Contents

This documentation page contains the following sections:

- The Transports section documents asyncio **`BaseTransport`**, **`ReadTransport`**, **`WriteTransport`**, **`Transport`**, **`DatagramTransport`**, and **`SubprocessTransport`** classes.
- The Protocols section documents asyncio **`BaseProtocol`**, **`Protocol`**, **`BufferedProtocol`**, **`DatagramProtocol`**, and **`SubprocessProtocol`** classes.
- The Examples section showcases how to work with transports, protocols, and low-level event loop APIs.

Transports

Source code: Lib/asyncio/transports.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/transports.py]

Transports are classes provided by **`asyncio`** in order to abstract various kinds of communication channels.

Transport objects are always instantiated by an asyncio event loop.

asyncio implements transports for TCP, UDP, SSL, and subprocess pipes. The methods available on a transport depend on the transport's kind.

The transport classes are not thread safe.

Transports Hierarchy

class asyncio.BaseTransport

Base class for all transports. Contains methods that all asyncio

transports share.

class asyncio.WriteTransport(*BaseTransport*)

A base transport for write-only connections.

Instances of the *WriteTransport* class are returned from the `loop.connect_write_pipe()` event loop method and are also used by subprocess-related methods like `loop.subprocess_exec()`.

class asyncio.ReadTransport(*BaseTransport*)

A base transport for read-only connections.

Instances of the *ReadTransport* class are returned from the `loop.connect_read_pipe()` event loop method and are also used by subprocess-related methods like `loop.subprocess_exec()`.

class asyncio.Transport(*WriteTransport*, *ReadTransport*)

Interface representing a bidirectional transport, such as a TCP connection.

The user does not instantiate a transport directly; they call a utility function, passing it a protocol factory and other information necessary to create the transport and protocol.

Instances of the *Transport* class are returned from or used by event loop methods like `loop.create_connection()`, `loop.create_unix_connection()`, `loop.create_server()`, `loop.sendfile()`, etc.

class asyncio.DatagramTransport(*BaseTransport*)

A transport for datagram (UDP) connections.

Instances of the *DatagramTransport* class are returned from the `loop.create_datagram_endpoint()` event loop method.

class asyncio.SubprocessTransport(*BaseTransport*)

An abstraction to represent a connection between a parent and its child OS process.

Instances of the *SubprocessTransport* class are returned from event loop methods **`loop.subprocess_shell()`** and **`loop.subprocess_exec()`**.

Base Transport

BaseTransport.close()

Close the transport.

If the transport has a buffer for outgoing data, buffered data will be flushed asynchronously. No more data will be received. After all buffered data is flushed, the protocol's **`protocol.connection_lost()`** method will be called with **`None`** as its argument. The transport should not be used once it is closed.

BaseTransport.is_closing()

Return `True` if the transport is closing or is closed.

BaseTransport.get_extra_info(*name*, *default*=*None*)

Return information about the transport or underlying resources it uses.

name is a string representing the piece of transport-specific information to get.

default is the value to return if the information is not available, or if the transport does not support querying it with the given third-party event loop implementation or on the current platform.

For example, the following code attempts to get the underlying socket object of the transport:

```
sock = transport.get_extra_info('socket')
if sock is not None:
```

```
print(sock.getsockopt(...))
```

Categories of information that can be queried on some transports:

- socket:
  - `'peername'`: the remote address to which the socket is connected, result of **`socket.socket.getpeername()`** (`None` on error)
  - `'socket'`: **`socket.socket`** instance
  - `'sockname'`: the socket's own address, result of **`socket.socket.getsockname()`**
- SSL socket:
  - `'compression'`: the compression algorithm being used as a string, or `None` if the connection isn't compressed; result of **`ssl.SSLSocket.compression()`**
  - `'cipher'`: a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used; result of **`ssl.SSLSocket.cipher()`**
  - `'peercert'`: peer certificate; result of **`ssl.SSLSocket.getpeercert()`**
  - `'sslcontext'`: **`ssl.SSLContext`** instance
  - `'ssl_object'`: **`ssl.SSLObject`** or **`ssl.SSLSocket`** instance
- pipe:
  - `'pipe'`: pipe object
- subprocess:
  - `'subprocess'`: **`subprocess.Popen`** instance

BaseTransport.set_protocol(*protocol*)

Set a new protocol.

Switching protocol should only be done when both protocols are documented to support the switch.

BaseTransport.get_protocol()

Return the current protocol.

Read-only Transports

ReadTransport.is_reading()

Return `True` if the transport is receiving new data.

New in version 3.7.

ReadTransport.pause_reading()

Pause the receiving end of the transport. No data will be passed to the protocol's **`protocol.data_received()`** method until **`resume_reading()`** is called.

Changed in version 3.7: The method is idempotent, i.e. it can be called when the transport is already paused or closed.

ReadTransport.resume_reading()

Resume the receiving end. The protocol's **`protocol.data_received()`** method will be called once again if some data is available for reading.

Changed in version 3.7: The method is idempotent, i.e. it can be called when the transport is already reading.

Write-only Transports

WriteTransport.abort()

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's **`protocol.connection_lost()`** method will eventually be called with **`None`** as its argument.

WriteTransport.can_write_eof()

Return **`True`** if the transport supports **`write_eof()`**, **`False`** if not.

WriteTransport.get_write_buffer_size()

Return the current size of the output buffer used by the transport.

WriteTransport.get_write_buffer_limits()

Get the *high* and *low* watermarks for write flow control. Return a tuple `(low, high)` where *low* and *high* are positive number of bytes.

Use **`set_write_buffer_limits()`** to set the limits.

New in version 3.4.2.

WriteTransport.set_write_buffer_limits(*high=None*, *low=None*)

Set the *high* and *low* watermarks for write flow control.

These two values (measured in number of bytes) control when the protocol's **`protocol.pause_writing()`** and **`protocol.resume_writing()`** methods are called. If specified, the low watermark must be less than or equal to the high watermark. Neither *high* nor *low* can be negative.

`pause_writing()` is called when the buffer size becomes greater than or equal to the *high* value. If writing has been paused, **`resume_writing()`** is called when the buffer size becomes less than or equal to the *low* value.

The defaults are implementation-specific. If only the high watermark is given, the low watermark defaults to an implementation-specific value less than or equal to the high watermark. Setting *high* to zero forces *low* to zero as well, and causes **`pause_writing()`** to be called whenever the buffer becomes non-empty. Setting *low* to zero causes **`resume_writing()`** to be called only once the buffer is empty. Use of zero for either limit is generally sub-optimal as it reduces opportunities for doing I/O and computation concurrently.

Use **`get_write_buffer_limits()`** to get the limits.

WriteTransport.write(*data*)

Write some *data* bytes to the transport.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

WriteTransport.writelines(*list_of_data*)

Write a list (or any iterable) of data bytes to the transport. This is functionally equivalent to calling `write()` on each element yielded by the iterable, but may be implemented more efficiently.

WriteTransport.write_eof()

Close the write end of the transport after flushing all buffered data. Data may still be received.

This method can raise `NotImplementedError` if the transport (e.g. SSL) doesn't support half-closed connections.

Datagram Transports

DatagramTransport.sendto(*data*, *addr*=*None*)

Send the *data* bytes to the remote peer given by *addr* (a transport-dependent target address). If *addr* is `None`, the data is sent to the target address given on transport creation.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

DatagramTransport.abort()

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's `protocol.connection_lost()` method will eventually be called with `None` as its argument.

Subprocess Transports

SubprocessTransport.get_pid()

Return the subprocess process id as an integer.

SubprocessTransport.get_pipe_transport(*fd*)

Return the transport for the communication pipe corresponding to the integer file descriptor *fd*:

- `0`: readable streaming transport of the standard input (*stdin*), or **`None`** if the subprocess was not created with `stdin=PIPE`
- `1`: writable streaming transport of the standard output (*stdout*), or **`None`** if the subprocess was not created with `stdout=PIPE`
- `2`: writable streaming transport of the standard error (*stderr*), or **`None`** if the subprocess was not created with `stderr=PIPE`
- other *fd*: **`None`**

SubprocessTransport.get_returncode()

Return the subprocess return code as an integer or **`None`** if it hasn't returned, which is similar to the **`subprocess.Popen.returncode`** attribute.

SubprocessTransport.kill()

Kill the subprocess.

On POSIX systems, the function sends SIGKILL to the subprocess. On Windows, this method is an alias for **`terminate()`**.

See also **`subprocess.Popen.kill()`**.

SubprocessTransport.send_signal(*signal*)

Send the *signal* number to the subprocess, as in **`subprocess.Popen.send_signal()`**.

SubprocessTransport.terminate()

Stop the subprocess.

On POSIX systems, this method sends SIGTERM to the subprocess. On Windows, the Windows API function TerminateProcess() is called to stop the subprocess.

See also `subprocess.Popen.terminate()`.

SubprocessTransport.close()

Kill the subprocess by calling the `kill()` method.

If the subprocess hasn't returned yet, and close transports of *stdin*, *stdout*, and *stderr* pipes.

Protocols

Source code: Lib/asyncio/protocols.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/protocols.py]

---

asyncio provides a set of abstract base classes that should be used to implement network protocols. Those classes are meant to be used together with transports.

Subclasses of abstract base protocol classes may implement some or all methods. All these methods are callbacks: they are called by transports on certain events, for example when some data is received. A base protocol method should be called by the corresponding transport.

Base Protocols

class asyncio.BaseProtocol

Base protocol with methods that all protocols share.

class asyncio.Protocol(*BaseProtocol*)

The base class for implementing streaming protocols (TCP, Unix sockets, etc).

class asyncio.BufferedProtocol(*BaseProtocol*)

A base class for implementing streaming protocols with manual control of the receive buffer.

class asyncio.DatagramProtocol(*BaseProtocol*)

The base class for implementing datagram (UDP) protocols.

class asyncio.SubprocessProtocol(*BaseProtocol*)

The base class for implementing protocols communicating with child processes (unidirectional pipes).

Base Protocol

All asyncio protocols can implement Base Protocol callbacks.

Connection Callbacks

Connection callbacks are called on all protocols, exactly once per a successful connection. All other protocol callbacks can only be called between those two methods.

BaseProtocol.connection_made(*transport*)

Called when a connection is made.

The *transport* argument is the transport representing the connection. The protocol is responsible for storing the reference to its transport.

BaseProtocol.connection_lost(*exc*)

Called when the connection is lost or closed.

The argument is either an exception object or `None`. The latter means a regular EOF is received, or the connection was aborted or closed by this side of the connection.

Flow Control Callbacks

Flow control callbacks can be called by transports to pause or resume writing performed by the protocol.

See the documentation of the **`set_write_buffer_limits()`** method for more details.

BaseProtocol.pause_writing()

Called when the transport's buffer goes over the high watermark.

BaseProtocol.resume_writing()

Called when the transport's buffer drains below the low watermark.

If the buffer size equals the high watermark, **`pause_writing()`** is not called: the buffer size must go strictly over.

Conversely, **`resume_writing()`** is called when the buffer size is equal or lower than the low watermark. These end conditions are important to ensure that things go as expected when either mark is zero.

Streaming Protocols

Event methods, such as **`loop.create_server()`**, **`loop.create_unix_server()`**, **`loop.create_connection()`**, **`loop.create_unix_connection()`**, **`loop.connect_accepted_socket()`**, **`loop.connect_read_pipe()`**, and **`loop.connect_write_pipe()`** accept factories that return streaming protocols.

Protocol.data_received(*data*)

Called when some data is received. *data* is a non-empty bytes object containing the incoming data.

Whether the data is buffered, chunked or reassembled depends on the transport. In general, you shouldn't rely on specific semantics and instead make your parsing generic and flexible. However, data is always received in the correct order.

The method can be called an arbitrary number of times while a connection is open.

However, **`protocol.eof_received()`** is called at most once. Once `eof_received()` is called, `data_received()` is not called anymore.

Protocol.eof_received()

Called when the other end signals it won't send any more data (for example by calling **`transport.write_eof()`**, if the other end also uses asyncio).

This method may return a false value (including `None`), in which case the transport will close itself. Conversely, if this method returns a true value, the protocol used determines whether to close the transport. Since the default implementation returns `None`, it implicitly closes the connection.

Some transports, including SSL, don't support half-closed connections, in which case returning true from this method will result in the connection being closed.

State machine:

```
start -> connection_made
    [-> data_received]*
    [-> eof_received]?
-> connection_lost -> end
```

Buffered Streaming Protocols

New in version 3.7.

Buffered Protocols can be used with any event loop method that supports Streaming Protocols.

`BufferedProtocol` implementations allow explicit manual allocation and control of the receive buffer. Event loops can then use the buffer provided by the protocol to avoid unnecessary data copies. This can result in noticeable performance improvement for protocols that receive big amounts of data. Sophisticated protocol implementations can significantly reduce the number of buffer allocations.

The following callbacks are called on **`BufferedProtocol`** instances:

BufferedProtocol.get_buffer(*sizehint*)

Called to allocate a new receive buffer.

sizehint is the recommended minimum size for the returned buffer. It is acceptable to return smaller or larger buffers than what *sizehint* suggests. When set to -1, the buffer size can be arbitrary. It is an error to return a buffer with a zero size.

`get_buffer()` must return an object implementing the buffer protocol.

BufferedProtocol.buffer_updated(*nbytes*)

Called when the buffer was updated with the received data.

nbytes is the total number of bytes that were written to the buffer.

BufferedProtocol.eof_received()

See the documentation of the **`protocol.eof_received()`** method.

`get_buffer()` can be called an arbitrary number of times during a connection. However, **`protocol.eof_received()`** is called at most once and, if called, **`get_buffer()`** and **`buffer_updated()`** won't be called after it.

State machine:

```
start -> connection_made
    [-> get_buffer
        [-> buffer_updated]?
    ]*
    [-> eof_received]?
-> connection_lost -> end
```

Datagram Protocols

Datagram Protocol instances should be constructed by protocol factories passed to the **`loop.create_datagram_endpoint()`** method.

DatagramProtocol.datagram_received(*data*, *addr*)

Called when a datagram is received. *data* is a bytes object containing the incoming data. *addr* is the address of the peer sending the data; the exact format depends on the transport.

DatagramProtocol.error_received(*exc*)

Called when a previous send or receive operation raises an **`OSError`**. *exc* is the **`OSError`** instance.

This method is called in rare conditions, when the transport (e.g. UDP) detects that a datagram could not be delivered to its recipient. In many conditions though, undeliverable datagrams will be silently dropped.

Note

On BSD systems (macOS, FreeBSD, etc.) flow control is not supported for datagram protocols, because there is no reliable way to detect send failures caused by writing too many packets.

The socket always appears 'ready' and excess packets are dropped. An **`OSError`** with `errno` set to **`errno.ENOBUFS`** may or may not be raised; if it is raised, it will be reported to **`DatagramProtocol.error_received()`** but otherwise

ignored.

Subprocess Protocols

Subprocess Protocol instances should be constructed by protocol factories passed to the **loop.subprocess_exec()** and **loop.subprocess_shell()** methods.

SubprocessProtocol.pipe_data_received(*fd*, *data*)

Called when the child process writes data into its stdout or stderr pipe.

fd is the integer file descriptor of the pipe.

data is a non-empty bytes object containing the received data.

SubprocessProtocol.pipe_connection_lost(*fd*, *exc*)

Called when one of the pipes communicating with the child process is closed.

fd is the integer file descriptor that was closed.

SubprocessProtocol.process_exited()

Called when the child process has exited.

Examples

TCP Echo Server

Create a TCP echo server using the **loop.create_server()** method, send back received data, and close the connection:

```
import asyncio

class EchoServerProtocol(asyncio.Protocol):
    def connection_made(self, transport):
        peername = transport.get_extra_info('peername')
```

```
        print('Connection from {}'.format(peername))
        self.transport = transport

    def data_received(self, data):
        message = data.decode()
        print('Data received: {!r}'.format(message))

        print('Send: {!r}'.format(message))
        self.transport.write(data)

        print('Close the client socket')
        self.transport.close()

async def main():
    # Get a reference to the event loop as we plan to us
    # low-level APIs.
    loop = asyncio.get_running_loop()

    server = await loop.create_server(
        lambda: EchoServerProtocol(),
        '127.0.0.1', 8888)

    async with server:
        await server.serve_forever()

asyncio.run(main())
```

See also

The TCP echo server using streams example uses the high-level **`asyncio.start_server()`** function.

TCP Echo Client

A TCP echo client using the **`loop.create_connection()`** method, sends data, and waits until the connection is closed:

```
import asyncio

class EchoClientProtocol(asyncio.Protocol):
    def __init__(self, message, on_con_lost):
        self.message = message
        self.on_con_lost = on_con_lost

    def connection_made(self, transport):
        transport.write(self.message.encode())
        print('Data sent: {!r}'.format(self.message))

    def data_received(self, data):
        print('Data received: {!r}'.format(data.decode()

    def connection_lost(self, exc):
        print('The server closed the connection')
        self.on_con_lost.set_result(True)

async def main():
    # Get a reference to the event loop as we plan to us
    # low-level APIs.
    loop = asyncio.get_running_loop()

    on_con_lost = loop.create_future()
    message = 'Hello World!'

    transport, protocol = await loop.create_connection(
        lambda: EchoClientProtocol(message, on_con_lost)
        '127.0.0.1', 8888)

    # Wait until the protocol signals that the connectio
    # is lost and close the transport.
    try:
        await on_con_lost
    finally:
        transport.close()
```

```
asyncio.run(main())
```

See also

The TCP echo client using streams example uses the high-level **`asyncio.open_connection()`** function.

UDP Echo Server

A UDP echo server, using the **`loop.create_datagram_endpoint()`** method, sends back received data:

```
import asyncio

class EchoServerProtocol:
    def connection_made(self, transport):
        self.transport = transport

    def datagram_received(self, data, addr):
        message = data.decode()
        print('Received %r from %s' % (message, addr))
        print('Send %r to %s' % (message, addr))
        self.transport.sendto(data, addr)

async def main():
    print("Starting UDP server")

    # Get a reference to the event loop as we plan to us
    # low-level APIs.
    loop = asyncio.get_running_loop()

    # One protocol instance will be created to serve all
    # client requests.
```

```
    transport, protocol = await loop.create_datagram_enc
        lambda: EchoServerProtocol(),
        local_addr=('127.0.0.1', 9999))

    try:
        await asyncio.sleep(3600)  # Serve for 1 hour.
    finally:
        transport.close()

asyncio.run(main())
```

UDP Echo Client

A UDP echo client, using the **`loop.create_datagram_endpoint()`** method, sends data and closes the transport when it receives the answer:

```
import asyncio

class EchoClientProtocol:
    def __init__(self, message, on_con_lost):
        self.message = message
        self.on_con_lost = on_con_lost
        self.transport = None

    def connection_made(self, transport):
        self.transport = transport
        print('Send:', self.message)
        self.transport.sendto(self.message.encode())

    def datagram_received(self, data, addr):
        print("Received:", data.decode())

        print("Close the socket")
        self.transport.close()

    def error_received(self, exc):
```

```
        print('Error received:', exc)

    def connection_lost(self, exc):
        print("Connection closed")
        self.on_con_lost.set_result(True)

async def main():
    # Get a reference to the event loop as we plan to us
    # low-level APIs.
    loop = asyncio.get_running_loop()

    on_con_lost = loop.create_future()
    message = "Hello World!"

    transport, protocol = await loop.create_datagram_enc
        lambda: EchoClientProtocol(message, on_con_lost)
        remote_addr=('127.0.0.1', 9999))

    try:
        await on_con_lost
    finally:
        transport.close()

asyncio.run(main())
```

Connecting Existing Sockets

Wait until a socket receives data using the **`loop.create_connection()`** method with a protocol:

```
import asyncio
import socket

class MyProtocol(asyncio.Protocol):

    def __init__(self, on_con_lost):
```

```
        self.transport = None
        self.on_con_lost = on_con_lost

    def connection_made(self, transport):
        self.transport = transport

    def data_received(self, data):
        print("Received:", data.decode())

        # We are done: close the transport;
        # connection_lost() will be called automatically
        self.transport.close()

    def connection_lost(self, exc):
        # The socket has been closed
        self.on_con_lost.set_result(True)

async def main():
    # Get a reference to the event loop as we plan to us
    # low-level APIs.
    loop = asyncio.get_running_loop()
    on_con_lost = loop.create_future()

    # Create a pair of connected sockets
    rsock, wsock = socket.socketpair()

    # Register the socket to wait for data.
    transport, protocol = await loop.create_connection(
        lambda: MyProtocol(on_con_lost), sock=rsock)

    # Simulate the reception of data from the network.
    loop.call_soon(wsock.send, 'abc'.encode())

    try:
        await protocol.on_con_lost
    finally:
        transport.close()
```

```
        wsock.close()

asyncio.run(main())
```

See also

The watch a file descriptor for read events example uses the low-level **`loop.add_reader()`** method to register an FD.

The register an open socket to wait for data using streams example uses high-level streams created by the **`open_connection()`** function in a coroutine.

loop.subprocess_exec() and SubprocessProtocol

An example of a subprocess protocol used to get the output of a subprocess and to wait for the subprocess exit.

The subprocess is created by the **`loop.subprocess_exec()`** method:

```
import asyncio
import sys

class DateProtocol(asyncio.SubprocessProtocol):
    def __init__(self, exit_future):
        self.exit_future = exit_future
        self.output = bytearray()

    def pipe_data_received(self, fd, data):
        self.output.extend(data)

    def process_exited(self):
        self.exit_future.set_result(True)

async def get_date():
    # Get a reference to the event loop as we plan to us
    # low-level APIs.
    loop = asyncio.get_running_loop()
```

```
    code = 'import datetime; print(datetime.datetime.now
    exit_future = asyncio.Future(loop=loop)

    # Create the subprocess controlled by DateProtocol;
    # redirect the standard output into a pipe.
    transport, protocol = await loop.subprocess_exec(
        lambda: DateProtocol(exit_future),
        sys.executable, '-c', code,
        stdin=None, stderr=None)

    # Wait for the subprocess exit using the process_exi
    # method of the protocol.
    await exit_future

    # Close the stdout pipe.
    transport.close()

    # Read the output which was collected by the
    # pipe_data_received() method of the protocol.
    data = bytes(protocol.output)
    return data.decode('ascii').rstrip()

date = asyncio.run(get_date())
print(f"Current date: {date}")
```

See also the same example written using high-level APIs.

Policies

An event loop policy is a global object used to get and set the current event loop, as well as create new event loops. The default policy can be replaced with built-in alternatives to use different event loop implementations, or substituted by a custom policy that can override these behaviors.

The policy object gets and sets a separate event loop per *context*. This is per-thread by default, though custom policies could define *context* differently.

Custom event loop policies can control the behavior of **`get_event_loop()`**, **`set_event_loop()`**, and **`new_event_loop()`**.

Policy objects should implement the APIs defined in the **`AbstractEventLoopPolicy`** abstract base class.

Getting and Setting the Policy

The following functions can be used to get and set the policy for the current process:

asyncio.get_event_loop_policy()

Return the current process-wide policy.

asyncio.set_event_loop_policy(*policy*)

Set the current process-wide policy to *policy*.

If *policy* is set to `None`, the default policy is restored.

Policy Objects

The abstract event loop policy base class is defined as follows:

class asyncio.AbstractEventLoopPolicy

An abstract base class for asyncio policies.

get_event_loop()

Get the event loop for the current context.

Return an event loop object implementing the **`AbstractEventLoop`** interface.

This method should never return `None`.

Changed in version 3.6.

set_event_loop(*loop*)

Set the event loop for the current context to *loop*.

new_event_loop()

Create and return a new event loop object.

This method should never return `None`.

get_child_watcher()

Get a child process watcher object.

Return a watcher object implementing the **`AbstractChildWatcher`** interface.

This function is Unix specific.

set_child_watcher(*watcher*)

Set the current child process watcher to *watcher*.

This function is Unix specific.

asyncio ships with the following built-in policies:

class asyncio.DefaultEventLoopPolicy

The default asyncio policy. Uses **SelectorEventLoop** on Unix and **ProactorEventLoop** on Windows.

There is no need to install the default policy manually. asyncio is configured to use the default policy automatically.

Changed in version 3.8: On Windows, **ProactorEventLoop** is now used by default.

Deprecated since version 3.11.1: **get_event_loop()** now emits a **DeprecationWarning** if there is no current event loop set and a new event loop has been implicitly created. In Python 3.12 it will be an error.

class asyncio.WindowsSelectorEventLoopPolicy

An alternative event loop policy that uses the **SelectorEventLoop** event loop implementation.

Availability: Windows.

class asyncio.WindowsProactorEventLoopPolicy

An alternative event loop policy that uses the **ProactorEventLoop** event loop implementation.

Availability: Windows.

Process Watchers

A process watcher allows customization of how an event loop monitors child processes on Unix. Specifically, the event loop needs to know when a child process has exited.

In asyncio, child processes are created with **create_subprocess_exec()** and **loop.subprocess_exec()** functions.

asyncio defines the **AbstractChildWatcher** abstract base class, which child watchers should implement, and has four different implementations: **ThreadedChildWatcher** (configured to be used by default), **MultiLoopChildWatcher**,

SafeChildWatcher, and **FastChildWatcher**.

See also the Subprocess and Threads section.

The following two functions can be used to customize the child process watcher implementation used by the asyncio event loop:

asyncio.get_child_watcher()

Return the current child watcher for the current policy.

asyncio.set_child_watcher(*watcher*)

Set the current child watcher to *watcher* for the current policy. *watcher* must implement methods defined in the **AbstractChildWatcher** base class.

Note

Third-party event loops implementations might not support custom child watchers. For such event loops, using **set_child_watcher()** might be prohibited or have no effect.

class asyncio.AbstractChildWatcher

add_child_handler(*pid*, *callback*, **args*)

Register a new child handler.

Arrange for `callback(pid, returncode, *args)` to be called when a process with PID equal to *pid* terminates. Specifying another callback for the same process replaces the previous handler.

The *callback* callable must be thread-safe.

remove_child_handler(*pid*)

Removes the handler for process with PID equal to *pid*.

The function returns `True` if the handler was successfully removed, `False` if there was nothing to

remove.

attach_loop(*loop*)

Attach the watcher to an event loop.

If the watcher was previously attached to an event loop, then it is first detached before attaching to the new loop.

Note: loop may be `None`.

is_active()

Return `True` if the watcher is ready to use.

Spawning a subprocess with *inactive* current child watcher raises **`RuntimeError`**.

New in version 3.8.

close()

Close the watcher.

This method has to be called to ensure that underlying resources are cleaned-up.

class asyncio.ThreadedChildWatcher

This implementation starts a new waiting thread for every subprocess spawn.

It works reliably even when the asyncio event loop is run in a non-main OS thread.

There is no noticeable overhead when handling a big number of children (*O(1)* each time a child terminates), but starting a thread per process requires extra memory.

This watcher is used by default.

New in version 3.8.

class asyncio.MultiLoopChildWatcher

This implementation registers a **SIGCHLD** signal handler on instantiation. That can break third-party code that installs a custom handler for **SIGCHLD** signal.

The watcher avoids disrupting other code spawning processes by polling every process explicitly on a **SIGCHLD** signal.

There is no limitation for running subprocesses from different threads once the watcher is installed.

The solution is safe but it has a significant overhead when handling a big number of processes (*O(n)* each time a **SIGCHLD** is received).

New in version 3.8.

class asyncio.SafeChildWatcher

This implementation uses active event loop from the main thread to handle **SIGCHLD** signal. If the main thread has no running event loop another thread cannot spawn a subprocess (**RuntimeError** is raised).

The watcher avoids disrupting other code spawning processes by polling every process explicitly on a **SIGCHLD** signal.

This solution is as safe as **MultiLoopChildWatcher** and has the same *O(N)* complexity but requires a running event loop in the main thread to work.

class asyncio.FastChildWatcher

This implementation reaps every terminated processes by calling `os.waitpid(-1)` directly, possibly breaking other code spawning processes and waiting for their termination.

There is no noticeable overhead when handling a big number of children (*O(1)* each time a child terminates).

This solution requires a running event loop in the main thread to work, as **SafeChildWatcher**.

class asyncio.PidfdChildWatcher

This implementation polls process file descriptors (pidfds) to await child process termination. In some respects, **PidfdChildWatcher** is a "Goldilocks" child watcher implementation. It doesn't require signals or threads, doesn't interfere with any processes launched outside the event loop, and scales linearly with the number of subprocesses launched by the event loop. The main disadvantage is that pidfds are specific to Linux, and only work on recent (5.3+) kernels.

New in version 3.9.

Custom Policies

To implement a new event loop policy, it is recommended to subclass **DefaultEventLoopPolicy** and override the methods for which custom behavior is wanted, e.g.:

```
class MyEventLoopPolicy(asyncio.DefaultEventLoopPolicy):

    def get_event_loop(self):
        """Get the event loop.

        This may be None or an instance of EventLoop.
        """
        loop = super().get_event_loop()
        # Do something with loop ...
        return loop

asyncio.set_event_loop_policy(MyEventLoopPolicy())
```

Platform Support

The **asyncio** module is designed to be portable, but some platforms have subtle differences and limitations due to the platforms' underlying architecture and capabilities.

All Platforms

- **loop.add_reader()** and **loop.add_writer()** cannot be used to monitor file I/O.

Windows

Source code: Lib/asyncio/proactor_events.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/proactor_events.py], Lib/asyncio/windows_events.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/windows_events.py], Lib/asyncio/windows_utils.py [https://github.com/python/cpython/tree/3.11/Lib/asyncio/windows_utils.py]

Changed in version 3.8: On Windows, **ProactorEventLoop** is now the default event loop.

All event loops on Windows do not support the following methods:

- **loop.create_unix_connection()** and **loop.create_unix_server()** are not supported. The **socket.AF_UNIX** socket family is specific to Unix.
- **loop.add_signal_handler()** and **loop.remove_signal_handler()** are not supported.

SelectorEventLoop has the following limitations:

- **SelectSelector** is used to wait on socket events: it supports sockets and is limited to 512 sockets.
- **loop.add_reader()** and **loop.add_writer()** only

accept socket handles (e.g. pipe file descriptors are not supported).
- Pipes are not supported, so the `loop.connect_read_pipe()` and `loop.connect_write_pipe()` methods are not implemented.
- Subprocesses are not supported, i.e. `loop.subprocess_exec()` and `loop.subprocess_shell()` methods are not implemented.

`ProactorEventLoop` has the following limitations:

- The `loop.add_reader()` and `loop.add_writer()` methods are not supported.

The resolution of the monotonic clock on Windows is usually around 15.6 milliseconds. The best resolution is 0.5 milliseconds. The resolution depends on the hardware (availability of HPET [https://en.wikipedia.org/wiki/High_Precision_Event_Timer]) and on the Windows configuration.

Subprocess Support on Windows

On Windows, the default event loop `ProactorEventLoop` supports subprocesses, whereas `SelectorEventLoop` does not.

The `policy.set_child_watcher()` function is also not supported, as `ProactorEventLoop` has a different mechanism to watch child processes.

macOS

Modern macOS versions are fully supported.

macOS <= 10.8

On macOS 10.6, 10.7 and 10.8, the default event loop uses `selectors.KqueueSelector`, which does not support character

devices on these versions. The **`SelectorEventLoop`** can be manually configured to use **`SelectSelector`** or **`PollSelector`** to support character devices on these older versions of macOS. Example:

```
import asyncio
import selectors

selector = selectors.SelectSelector()
loop = asyncio.SelectorEventLoop(selector)
asyncio.set_event_loop(loop)
```

Extending

The main direction for **asyncio** extending is writing custom *event loop* classes. Asyncio has helpers that could be used to simplify this task.

Note

Third-parties should reuse existing asyncio code with caution, a new Python version is free to break backward compatibility in *internal* part of API.

Writing a Custom Event Loop

asyncio.AbstractEventLoop declares very many methods. Implementing all them from scratch is a tedious job.

A loop can get many common methods implementation for free by inheriting from **asyncio.BaseEventLoop**.

In turn, the successor should implement a bunch of *private* methods declared but not implemented in **asyncio.BaseEventLoop**.

For example, `loop.create_connection()` checks arguments, resolves DNS addresses, and calls `loop._make_socket_transport()` that should be implemented by inherited class. The `_make_socket_transport()` method is not documented and is considered as an *internal* API.

Future and Task private constructors

asyncio.Future and **asyncio.Task** should be never created directly, please use corresponding **loop.create_future()** and **loop.create_task()**, or **asyncio.create_task()** factories instead.

However, third-party *event loops* may *reuse* built-in future and task implementations for the sake of getting a complex and highly optimized code for free.

For this purpose the following, *private* constructors are listed:

Future._init_(*, *loop*=*None*)

Create a built-in future instance.

loop is an optional event loop instance.

Task._init_(*coro*, *, *loop*=*None*, *name*=*None*, *context*=*None*)

Create a built-in task instance.

loop is an optional event loop instance. The rest of arguments are described in **loop.create_task()** description.

Changed in version 3.11: context argument is added.

Task lifetime support

A third party task implementation should call the following functions to keep a task visible by **asyncio.get_tasks()** and **asyncio.current_task()**:

asyncio._register_task(*task*)

Register a new *task* as managed by *asyncio*.

Call the function from a task constructor.

asyncio._unregister_task(*task*)

Unregister a *task* from *asyncio* internal structures.

The function should be called when a task is about to finish.

asyncio._enter_task(*loop*, *task*)

Switch the current task to the *task* argument.

Call the function just before executing a portion of embedded *coroutine* (`coroutine.send()` or `coroutine.throw()`).

asyncio._leave_task(*loop*, *task*)

Switch the current task back from *task* to `None`.

Call the function just after `coroutine.send()` or `coroutine.throw()` execution.

High-level API Index

This page lists all high-level async/await enabled asyncio APIs.

Tasks

Utilities to run asyncio programs, create Tasks, and await on multiple things with timeouts.

`run()`	Create event loop, run a coroutine, close the loop.
`TaskGroup`	A context manager that simplifies multiple async function calls.
`Task`	Task object.
`TaskGroup`	A context manager that holds a group of tasks. Provides a convenient and reliable way to wait for all tasks in the group to finish.
`create_task()`	Start an asyncio Task, then returns it.
`current_task()`	Return the current Task.
`all_tasks()`	Return all tasks that are not yet finished for an event loop.
`sleep()`	Sleep for a number of seconds.
`gather()`	Schedule and wait for things concurrently.
`wait_for()`	Run with a timeout.
`shield()`	Shield from cancellation.
`wait()`	Monitor for completion.
`timeout()`	Run with a timeout. Useful in cases when `wait_for` is not suitable.
`to_thread()`	Asynchronously run a function in a separate OS thread.
`run_coroutine_threadsafe()`	Schedule a coroutine from another OS thread.
`as_completed()`	Monitor for completion with a `for` loop.

Examples

- Using asyncio.gather() to run things in parallel.
- Using asyncio.wait_for() to enforce a timeout.
- Cancellation.

- Using asyncio.sleep().
- See also the main Tasks documentation page.

Queues

Queues should be used to distribute work amongst multiple asyncio Tasks, implement connection pools, and pub/sub patterns.

Queue	A FIFO queue.
PriorityQueue	A priority queue.
LifoQueue	A LIFO queue.

Examples

- Using asyncio.Queue to distribute workload between several Tasks.
- See also the Queues documentation page.

Subprocesses

Utilities to spawn subprocesses and run shell commands.

create_subprocess_exec()	Create a subprocess.
create_subprocess_shell()	Run a shell command.

Examples

- Executing a shell command.
- See also the subprocess APIs documentation.

Streams

High-level APIs to work with network IO.

open_connection()	Establish a TCP connection.
open_unix_connection()	Establish a Unix socket connection.
start_server()	Start a TCP server.

`start_unix_server()`	Start a Unix socket server.
`StreamReader`	High-level async/await object to receive network data.
`StreamWriter`	High-level async/await object to send network data.

Examples

- Example TCP client.
- See also the streams APIs documentation.

Synchronization

Threading-like synchronization primitives that can be used in Tasks.

`Lock`	A mutex lock.
`Event`	An event object.
`Condition`	A condition object.
`Semaphore`	A semaphore.
`BoundedSemaphore`	A bounded semaphore.
`Barrier`	A barrier object.

Examples

- Using asyncio.Event.
- Using asyncio.Barrier.
- See also the documentation of asyncio synchronization primitives.

Exceptions

`asyncio.CancelledError`	Raised when a Task is cancelled. See also `Task.cancel()`.
`asyncio.BrokenBarrierError`	Raised when a Barrier is broken. See also `Barrier.wait()`.

Examples

- Handling CancelledError to run code on cancellation request.
- See also the full list of asyncio-specific exceptions.

Low-level API Index

This page lists all low-level asyncio APIs.

Obtaining the Event Loop

`asyncio.get_running_loop()`	The preferred function to get the running event loop.
`asyncio.get_event_loop()`	Get an event loop instance (running or current via the current policy).
`asyncio.set_event_loop()`	Set the event loop as current via the current policy.
`asyncio.new_event_loop()`	Create a new event loop.

Examples

- Using asyncio.get_running_loop().

Event Loop Methods

See also the main documentation section about the Event Loop Methods.

Lifecycle

`loop.run_until_complete()`	Run a Future/Task/awaitable until complete.
`loop.run_forever()`	Run the event loop forever.
`loop.stop()`	Stop the event loop.
`loop.close()`	Close the event loop.
`loop.is_running()`	Return `True` if the event loop is running.
`loop.is_closed()`	Return `True` if the event loop is closed.
`loop.shutdown_asyncgens()`	Close asynchronous generators.

Debugging

`loop.set_debug()`	Enable or disable the debug mode.
`loop.get_debug()`	Get the current debug mode.

Scheduling Callbacks

`loop.call_soon()`	Invoke a callback soon.
`loop.call_soon_threadsafe()`	A thread-safe variant of `loop.call_soon()`.
`loop.call_later()`	Invoke a callback *after* the given time.
`loop.call_at()`	Invoke a callback *at* the given time.

Thread/Process Pool

`loop.run_in_executor()`	Run a CPU-bound or other blocking function in a `concurrent.futures` executor.
`loop.set_default_executor()`	Set the default executor for `loop.run_in_executor()`.

Tasks and Futures

`loop.create_future()`	Create a `Future` object.
`loop.create_task()`	Schedule coroutine as a `Task`.
`loop.set_task_factory()`	Set a factory used by `loop.create_task()` to create `Tasks`.
`loop.get_task_factory()`	Get the factory `loop.create_task()` uses to create `Tasks`.

DNS

`loop.getaddrinfo()`	Asynchronous version of `socket.getaddrinfo()`.
`loop.getnameinfo()`	Asynchronous version of `socket.getnameinfo()`.

Networking and IPC

`loop.create_connection()`	Open a TCP connection.
`loop.create_server()`	Create a TCP server.
`loop.create_unix_connection()`	Open a Unix socket connection.

Create a Unix socket server.	`loop.create_unix_server()`
Wrap a `socket` into a `(transport, protocol)` pair.	`loop.connect_accepted_socket()`
Open a datagram (UDP) connection.	`loop.create_datagram_endpoint()`
Send a file over a transport.	`loop.sendfile()`
Upgrade an existing connection to TLS.	`loop.start_tls()`
Wrap a read end of a pipe into a `(transport, protocol)` pair.	`loop.connect_read_pipe()`
Wrap a write end of a pipe into a `(transport, protocol)` pair.	`loop.connect_write_pipe()`

Sockets

Receive data from the `socket`.	`loop.sock_recv()`
Receive data from the `socket` into a buffer.	`loop.sock_recv_into()`
Receive a datagram from the `socket`.	`loop.sock_recvfrom()`
Receive a datagram from the `socket` into a buffer.	`loop.sock_recvfrom_into()`
Send data to the `socket`.	`loop.sock_sendall()`
Send a datagram via the `socket` to the given address.	`loop.sock_sendto()`
Connect the `socket`.	`loop.sock_connect()`
Accept a connection.	`loop.sock_accept()`
Send a file over the `socket`.	`loop.sock_sendfile()`
Start watching a file descriptor for read availability.	`loop.add_reader()`
Stop watching a file descriptor for read availability.	`loop.remove_reader()`
Start watching a file descriptor for write availability.	`loop.add_writer()`
Stop watching a file descriptor for write availability.	`loop.remove_writer()`

Unix Signals

Add a handler for a signal.	`loop.add_signal_handler()`
Remove a handler for a signal.	`loop.remove_signal_handler()`

Subprocesses

Spawn a subprocess.	`loop.subprocess_exec()`
Spawn a subprocess from a shell command.	`loop.subprocess_shell()`

Error Handling

`call_exception_handler()`	Call the exception handler.
`set_exception_handler()`	Set a new exception handler.
`get_exception_handler()`	Get the current exception handler.
`default_exception_handler()`	The default exception handler implementation.

Examples

- Using asyncio.new_event_loop() and loop.run_forever().
- Using loop.call_later().
- Using `loop.create_connection()` to implement an echo-client.
- Using `loop.create_connection()` to connect a socket.
- Using add_reader() to watch an FD for read events.
- Using loop.add_signal_handler().
- Using loop.subprocess_exec().

Transports

All transports implement the following methods:

`close()`	Close the transport.
`is_closing()`	Return `True` if the transport is closing or is closed.
`get_extra_info()`	Request for information about the transport.
`set_protocol()`	Set a new protocol.
`get_protocol()`	Return the current protocol.

Transports that can receive data (TCP and Unix connections, pipes, etc). Returned from methods like `loop.create_connection()`, `loop.create_unix_connection()`, `loop.connect_read_pipe()`, etc:

Read Transports

`is_reading()`	Return `True` if the transport is receiving.
`pause_reading()`	Pause receiving.
`resume_reading()`	Resume receiving.

Transports that can Send data (TCP and Unix connections, pipes, etc). Returned from methods like `loop.create_connection()`, `loop.create_unix_connection()`, `loop.connect_write_pipe()`, etc:

Write Transports

`write(data)`	Write data to the transport.
`writelines(list_of_data)`	Write buffers to the transport.
`can_write_eof()`	Return `True` if the transport supports sending EOF.
`write_eof()`	Close and send EOF after flushing buffered data.
`close()`	Close the transport immediately.
`get_write_buffer_size()`	Return the current size of the output buffer.
`get_write_buffer_limits()`	Return high and low water marks for write flow control.
`set_write_buffer_limits(high, low)`	Set new high and low water marks for write flow control.

Transports returned by `loop.create_datagram_endpoint()`:

Datagram Transports

`sendto(data, addr=None)`	Send data to the remote peer.
`close()`	Close the transport immediately.

Low-level transport abstraction over subprocesses. Returned by `loop.subprocess_exec()` and `loop.subprocess_shell()`:

Subprocess Transports

`get_pid()`	Return the subprocess process id.
`get_pipe_transport(fd)`	Return the transport for the requested communication pipe (*stdin*, *stdout*, or *stderr*).
`get_returncode()`	Return the subprocess return code.
`kill()`	Kill the subprocess.
`send_signal(signal)`	Send a signal to the subprocess.
`terminate()`	Stop the subprocess.
`close()`	Kill the subprocess and close all pipes.

Protocols

Protocol classes can implement the following **callback methods**:

`connection_made()`	Called when a connection is made.
`connection_lost()`	Called when the connection is lost or closed.
`pause_writing()`	Called when the transport's buffer goes over the high water mark.
`resume_writing()`	Called when the transport's buffer drains below the low water mark.

Streaming Protocols (TCP, Unix Sockets, Pipes)

`data_received()`	Called when some data is received.
`eof_received()`	Called when an EOF is received.

Buffered Streaming Protocols

`get_buffer()`	Called to allocate a new receive buffer.
`buffer_updated()`	Called when the buffer was updated with the received data.
`eof_received()`	Called when an EOF is received.

Datagram Protocols

`datagram_received()`	Called when a datagram is received.
`error_received()`	Called when a previous send or receive operation raises an `OSError`.

Subprocess Protocols

`pipe_data_received()`	Called when the child process writes data into its *stdout* or *stderr* pipe.
`pipe_connection_lost()`	Called when one of the pipes communicating with the child process is closed.
`process_exited()`	Called when the child process has exited.

Event Loop Policies

Policies is a low-level mechanism to alter the behavior of functions like `asyncio.get_event_loop()`. See also the main policies section for more details.

Accessing Policies

`asyncio.get_event_loop_policy()`	Return the current process-wide policy.
`asyncio.set_event_loop_policy()`	Set a new process-wide policy.
`asyncio.AbstractEventLoopPolicy`	Base class for policy objects.

Developing with asyncio

Asynchronous programming is different from classic "sequential" programming.

This page lists common mistakes and traps and explains how to avoid them.

Debug Mode

By default asyncio runs in production mode. In order to ease the development asyncio has a *debug mode*.

There are several ways to enable asyncio debug mode:

- Setting the **`PYTHONASYNCIODEBUG`** environment variable to `1`.
- Using the Python Development Mode.
- Passing `debug=True` to **`asyncio.run()`**.
- Calling **`loop.set_debug()`**.

In addition to enabling the debug mode, consider also:

- setting the log level of the asyncio logger to **`logging.DEBUG`**, for example the following snippet of code can be run at startup of the application:

  ```
  logging.basicConfig(level=logging.DEBUG)
  ```

- configuring the **`warnings`** module to display **`ResourceWarning`** warnings. One way of doing that is by using the **`-W`** `default` command line option.

When the debug mode is enabled:

- asyncio checks for coroutines that were not awaited and logs them; this mitigates the "forgotten await" pitfall.

- Many non-threadsafe asyncio APIs (such as `loop.call_soon()` and `loop.call_at()` methods) raise an exception if they are called from a wrong thread.
- The execution time of the I/O selector is logged if it takes too long to perform an I/O operation.
- Callbacks taking longer than 100 milliseconds are logged. The `loop.slow_callback_duration` attribute can be used to set the minimum execution duration in seconds that is considered “slow”.

Concurrency and Multithreading

An event loop runs in a thread (typically the main thread) and executes all callbacks and Tasks in its thread. While a Task is running in the event loop, no other Tasks can run in the same thread. When a Task executes an `await` expression, the running Task gets suspended, and the event loop executes the next Task.

To schedule a callback from another OS thread, the `loop.call_soon_threadsafe()` method should be used. Example:

```
loop.call_soon_threadsafe(callback, *args)
```

Almost all asyncio objects are not thread safe, which is typically not a problem unless there is code that works with them from outside of a Task or a callback. If there’s a need for such code to call a low-level asyncio API, the `loop.call_soon_threadsafe()` method should be used, e.g.:

```
loop.call_soon_threadsafe(fut.cancel)
```

To schedule a coroutine object from a different OS thread, the `run_coroutine_threadsafe()` function should be used. It returns a `concurrent.futures.Future` to access the result:

```
async def coro_func():
     return await asyncio.sleep(1, 42)

# Later in another OS thread:
```

```
future = asyncio.run_coroutine_threadsafe(coro_func(), l
# Wait for the result:
result = future.result()
```

To handle signals and to execute subprocesses, the event loop must be run in the main thread.

The **`loop.run_in_executor()`** method can be used with a **`concurrent.futures.ThreadPoolExecutor`** to execute blocking code in a different OS thread without blocking the OS thread that the event loop runs in.

There is currently no way to schedule coroutines or callbacks directly from a different process (such as one started with **`multiprocessing`**). The Event Loop Methods section lists APIs that can read from pipes and watch file descriptors without blocking the event loop. In addition, asyncio's Subprocess APIs provide a way to start a process and communicate with it from the event loop. Lastly, the aforementioned **`loop.run_in_executor()`** method can also be used with a **`concurrent.futures.ProcessPoolExecutor`** to execute code in a different process.

Running Blocking Code

Blocking (CPU-bound) code should not be called directly. For example, if a function performs a CPU-intensive calculation for 1 second, all concurrent asyncio Tasks and IO operations would be delayed by 1 second.

An executor can be used to run a task in a different thread or even in a different process to avoid blocking the OS thread with the event loop. See the **`loop.run_in_executor()`** method for more details.

Logging

asyncio uses the **`logging`** module and all logging is performed via

the `"asyncio"` logger.

The default log level is **`logging.INFO`**, which can be easily adjusted:

```
logging.getLogger("asyncio").setLevel(logging.WARNING)
```

Network logging can block the event loop. It is recommended to use a separate thread for handling logs or use non-blocking IO. For example, see Dealing with handlers that block.

Detect never-awaited coroutines

When a coroutine function is called, but not awaited (e.g. `coro()` instead of `await coro()`) or the coroutine is not scheduled with **`asyncio.create_task()`**, asyncio will emit a **`RuntimeWarning`**:

```
import asyncio

async def test():
    print("never scheduled")

async def main():
    test()

asyncio.run(main())
```

Output:

```
test.py:7: RuntimeWarning: coroutine 'test' was never aw
  test()
```

Output in debug mode:

```
test.py:7: RuntimeWarning: coroutine 'test' was never aw
Coroutine created at (most recent call last)
  File "../t.py", line 9, in <module>
    asyncio.run(main(), debug=True)
```

```
  < .. >

  File "../t.py", line 7, in main
    test()
  test()
```

The usual fix is to either await the coroutine or call the **`asyncio.create_task()`** function:

```
async def main():
    await test()
```

Detect never-retrieved exceptions

If a **`Future.set_exception()`** is called but the Future object is never awaited on, the exception would never be propagated to the user code. In this case, asyncio would emit a log message when the Future object is garbage collected.

Example of an unhandled exception:

```
import asyncio

async def bug():
    raise Exception("not consumed")

async def main():
    asyncio.create_task(bug())

asyncio.run(main())
```

Output:

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at test
  exception=Exception('not consumed')>

Traceback (most recent call last):
  File "test.py", line 4, in bug
```

```
    raise Exception("not consumed")
Exception: not consumed
```

Enable the debug mode to get the traceback where the task was created:

```
asyncio.run(main(), debug=True)
```

Output in debug mode:

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at test
    exception=Exception('not consumed') created at asyn

source_traceback: Object created at (most recent call la
  File "../t.py", line 9, in <module>
    asyncio.run(main(), debug=True)

< .. >

Traceback (most recent call last):
  File "../t.py", line 4, in bug
    raise Exception("not consumed")
Exception: not consumed
```

`socket` — Low-level networking interface

Source code: Lib/socket.py [https://github.com/python/cpython/tree/3.11/Lib/socket.py]

This module provides access to the BSD *socket* interface. It is available on all modern Unix systems, Windows, MacOS, and probably additional platforms.

Note

Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python's object-oriented style: the **`socket()`** function returns a *socket object* whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface: as with **`read()`** and **`write()`** operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

See also

Module `socketserver`

Classes that simplify writing network servers.

Module **`ssl`**
A TLS/SSL wrapper for socket objects.

Socket families

Depending on the system and the build options, various socket families are supported by this module.

The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created. Socket addresses are represented as follows:

- The address of an **`AF_UNIX`** socket bound to a file system node is represented as a string, using the file system encoding and the `'surrogateescape'` error handler (see **PEP 383** [https://peps.python.org/pep-0383/]). An address in Linux's abstract namespace is returned as a bytes-like object with an initial null byte; note that sockets in this namespace can communicate with normal file system sockets, so programs intended to run on Linux may need to deal with both types of address. A string or bytes-like object can be used for either type of address when passing it as an argument.

  Changed in version 3.3: Previously, **`AF_UNIX`** socket paths were assumed to use UTF-8 encoding.

  Changed in version 3.5: Writable bytes-like object is now accepted.

- A pair `(host, port)` is used for the **`AF_INET`** address family, where *host* is a string representing either a hostname in internet domain notation like `'daring.cwi.nl'` or an IPv4 address like `'100.50.200.5'`, and *port* is an integer.

  - For IPv4 addresses, two special forms are accepted instead of a host address: `''` represents **`INADDR_ANY`**, which is used to bind to all interfaces, and the string

`'<broadcast>'` represents **`INADDR_BROADCAST`**. This behavior is not compatible with IPv6, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

- For **`AF_INET6`** address family, a four-tuple `(host, port, flowinfo, scope_id)` is used, where *flowinfo* and *scope_id* represent the `sin6_flowinfo` and `sin6_scope_id` members in **`struct sockaddr_in6`** in C. For **`socket`** module methods, *flowinfo* and *scope_id* can be omitted just for backward compatibility. Note, however, omission of *scope_id* can cause problems in manipulating scoped IPv6 addresses.

  Changed in version 3.7: For multicast addresses (with *scope_id* meaningful) *address* may not contain `%scope_id` (or `zone id`) part. This information is superfluous and may be safely omitted (recommended).

- **`AF_NETLINK`** sockets are represented as pairs `(pid, groups)`.

- Linux-only support for TIPC is available using the **`AF_TIPC`** address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is `(addr_type, v1, v2, v3 [, scope])`, where:

  - *addr_type* is one of **`TIPC_ADDR_NAMESEQ`**, **`TIPC_ADDR_NAME`**, or **`TIPC_ADDR_ID`**.

  - *scope* is one of **`TIPC_ZONE_SCOPE`**, **`TIPC_CLUSTER_SCOPE`**, and **`TIPC_NODE_SCOPE`**.

  - If *addr_type* is **`TIPC_ADDR_NAME`**, then *v1* is the server type, *v2* is the port identifier, and *v3* should be 0.

    If *addr_type* is **`TIPC_ADDR_NAMESEQ`**, then *v1* is the server type, *v2* is the lower port number, and *v3* is the upper port number.

If *addr_type* is **TIPC_ADDR_ID**, then *v1* is the node, *v2* is the reference, and *v3* should be set to 0.

- A tuple `(interface, )` is used for the **AF_CAN** address family, where *interface* is a string representing a network interface name like `'can0'`. The network interface name `''` can be used to receive packets from all network interfaces of this family.

    - **CAN_ISOTP** protocol require a tuple `(interface, rx_addr, tx_addr)` where both additional parameters are unsigned long integer that represent a CAN identifier (standard or extended).
    - **CAN_J1939** protocol require a tuple `(interface, name, pgn, addr)` where additional parameters are 64-bit unsigned integer representing the ECU name, a 32-bit unsigned integer representing the Parameter Group Number (PGN), and an 8-bit integer representing the address.

- A string or a tuple `(id, unit)` is used for the **SYSPROTO_CONTROL** protocol of the **PF_SYSTEM** family. The string is the name of a kernel control using a dynamically assigned ID. The tuple can be used if ID and unit number of the kernel control are known or if a registered ID is used.

  New in version 3.3.

- **AF_BLUETOOTH** supports the following protocols and address formats:

    - **BTPROTO_L2CAP** accepts `(bdaddr, psm)` where `bdaddr` is the Bluetooth address as a string and `psm` is an integer.

    - **BTPROTO_RFCOMM** accepts `(bdaddr, channel)` where `bdaddr` is the Bluetooth address as a string and `channel` is an integer.

    - **BTPROTO_HCI** accepts `(device_id,)` where `device_id` is either an integer or a string with the

Bluetooth address of the interface. (This depends on your OS; NetBSD and DragonFlyBSD expect a Bluetooth address while everything else expects an integer.)

Changed in version 3.2: NetBSD and DragonFlyBSD support added.

- **BTPROTO_SCO** accepts `bdaddr` where `bdaddr` is a **bytes** object containing the Bluetooth address in a string format. (ex. `b'12:23:34:45:56:67'`) This protocol is not supported under FreeBSD.

- **AF_ALG** is a Linux-only socket based interface to Kernel cryptography. An algorithm socket is configured with a tuple of two to four elements `(type, name [, feat [, mask]])`, where:

  - *type* is the algorithm type as string, e.g. `aead`, `hash`, `skcipher` or `rng`.
  - *name* is the algorithm name and operation mode as string, e.g. `sha256`, `hmac(sha256)`, `cbc(aes)` or `drbg_nopr_ctr_aes256`.
  - *feat* and *mask* are unsigned 32bit integers.

  Availability: Linux >= 2.6.38.

  Some algorithm types require more recent Kernels.

  New in version 3.6.

- **AF_VSOCK** allows communication between virtual machines and their hosts. The sockets are represented as a `(CID, port)` tuple where the context ID or CID and port are integers.

  Availability: Linux >= 3.9

  See *vsock(7)*

  New in version 3.7.

- **AF_PACKET** is a low-level interface directly to network devices. The packets are represented by the tuple `(ifname, proto[, pkttype[, hatype[, addr]]])` where:

  - *ifname* - String specifying the device name.
  - *proto* - An in network-byte-order integer specifying the Ethernet protocol number.
  - *pkttype* - Optional integer specifying the packet type:
    - `PACKET_HOST` (the default) - Packet addressed to the local host.
    - `PACKET_BROADCAST` - Physical-layer broadcast packet.
    - `PACKET_MULTICAST` - Packet sent to a physical-layer multicast address.
    - `PACKET_OTHERHOST` - Packet to some other host that has been caught by a device driver in promiscuous mode.
    - `PACKET_OUTGOING` - Packet originating from the local host that is looped back to a packet socket.
  - *hatype* - Optional integer specifying the ARP hardware address type.
  - *addr* - Optional bytes-like object specifying the hardware physical address, whose interpretation depends on the device.

  Availability: Linux >= 2.2.

- **AF_QIPCRTR** is a Linux-only socket based interface for communicating with services running on co-processors in Qualcomm platforms. The address family is represented as a `(node, port)` tuple where the *node* and *port* are non-negative integers.

  Availability: Linux >= 4.7.

  New in version 3.8.

- **IPPROTO_UDPLITE** is a variant of UDP which allows you to specify what portion of a packet is covered with the checksum. It adds two socket options that you can change. `self.setsockopt(IPPROTO_UDPLITE,`

`UDPLITE_SEND_CSCOV, length)` will change what portion of outgoing packets are covered by the checksum and `self.setsockopt(IPPROTO_UDPLITE, UDPLITE_RECV_CSCOV, length)` will filter out packets which cover too little of their data. In both cases `length` should be in `range(8, 2**16, 8)`.

Such a socket should be constructed with `socket(AF_INET, SOCK_DGRAM, IPPROTO_UDPLITE)` for IPv4 or `socket(AF_INET6, SOCK_DGRAM, IPPROTO_UDPLITE)` for IPv6.

Availability: Linux >= 2.6.20, FreeBSD >= 10.1

New in version 3.9.

If you use a hostname in the *host* portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in *host* portion.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised. Errors related to socket or address semantics raise **`OSError`** or one of its subclasses.

Non-blocking mode is supported through **`setblocking()`**. A generalization of this based on timeouts is supported through **`settimeout()`**.

Module contents

The module **`socket`** exports the following elements.

Exceptions

exception socket.error

A deprecated alias of **OSError**.

Changed in version 3.3: Following **PEP 3151** [https://peps.python.org/pep-3151/], this class was made an alias of **OSError**.

exception socket.herror

A subclass of **OSError**, this exception is raised for address-related errors, i.e. for functions that use *h_errno* in the POSIX C API, including **gethostbyname_ex()** and **gethostbyaddr()**. The accompanying value is a pair `(h_errno, string)` representing an error returned by a library call. *h_errno* is a numeric value, while *string* represents the description of *h_errno*, as returned by the **hstrerror()** C function.

Changed in version 3.3: This class was made a subclass of **OSError**.

exception socket.gaierror

A subclass of **OSError**, this exception is raised for address-related errors by **getaddrinfo()** and **getnameinfo()**. The accompanying value is a pair `(error, string)` representing an error returned by a library call. *string* represents the description of *error*, as returned by the **gai_strerror()** C function. The numeric *error* value will match one of the **EAI_*** constants defined in this module.

Changed in version 3.3: This class was made a subclass of **OSError**.

exception socket.timeout

A deprecated alias of **TimeoutError**.

A subclass of **OSError**, this exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to **settimeout()** (or implicitly through **setdefaulttimeout()**). The accompanying value is a string whose value is currently always “timed out”.

Changed in version 3.3: This class was made a subclass of **OSError**.

Changed in version 3.10: This class was made an alias of **TimeoutError**.

Constants

The AF_* and SOCK_* constants are now **AddressFamily** and **SocketKind** **IntEnum** collections.

New in version 3.4.

socket.AF_UNIX
socket.AF_INET
socket.AF_INET6

These constants represent the address (and protocol) families, used for the first argument to **socket()**. If the **AF_UNIX** constant is not defined then this protocol is unsupported. More constants may be available depending on the system.

socket.SOCK_STREAM
socket.SOCK_DGRAM
socket.SOCK_RAW
socket.SOCK_RDM
socket.SOCK_SEQPACKET

These constants represent the socket types, used for the second argument to **socket()**. More constants may be available depending on the system. (Only **SOCK_STREAM** and **SOCK_DGRAM** appear to be generally useful.)

socket.SOCK_CLOEXEC
socket.SOCK_NONBLOCK

These two constants, if defined, can be combined with the socket types and allow you to set some flags atomically (thus avoiding possible race conditions and the need for separate calls).

See also

Secure File Descriptor Handling [https://udrepper.livejournal.com/20407.html] for a more thorough explanation.

Availability: Linux >= 2.6.27.

New in version 3.2.

SO_*
socket.SOMAXCONN
MSG_*
SOL_*
SCM_*
IPPROTO_*
IPPORT_*
INADDR_*
IP_*
IPV6_*
EAI_*
AI_*
NI_*
TCP_*

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the **`setsockopt()`** and **`getsockopt()`** methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

Changed in version 3.6: `SO_DOMAIN`, `SO_PROTOCOL`, `SO_PEERSEC`, `SO_PASSSEC`, `TCP_USER_TIMEOUT`, `TCP_CONGESTION` were added.

Changed in version 3.6.5: On Windows, `TCP_FASTOPEN`, `TCP_KEEPCNT` appear if run-time Windows supports.

Changed in version 3.7: `TCP_NOTSENT_LOWAT` was added.

On Windows, `TCP_KEEPIDLE`, `TCP_KEEPINTVL` appear if run-time Windows supports.

Changed in version 3.10: `IP_RECVTOS` was added. Added `TCP_KEEPALIVE`. On MacOS this constant can be used in the same way that `TCP_KEEPIDLE` is used on Linux.

Changed in version 3.11: Added `TCP_CONNECTION_INFO`. On MacOS this constant can be used in the same way that `TCP_INFO` is used on Linux and BSD.

socket.AF_CAN
socket.PF_CAN
SOL_CAN_*
CAN_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.25, NetBSD >= 8.

New in version 3.3.

Changed in version 3.11: NetBSD support was added.

socket.CAN_BCM
CAN_BCM_*

CAN_BCM, in the CAN protocol family, is the broadcast manager (BCM) protocol. Broadcast manager constants, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.25.

Note

The **`CAN_BCM_CAN_FD_FRAME`** flag is only available on Linux >= 4.8.

New in version 3.4.

socket.CAN_RAW_FD_FRAMES

Enables CAN FD support in a CAN_RAW socket. This is disabled by default. This allows your application to send both CAN and CAN FD frames; however, you must accept both CAN and CAN FD frames when reading from the socket.

This constant is documented in the Linux documentation.

Availability: Linux >= 3.6.

New in version 3.5.

socket.CAN_RAW_JOIN_FILTERS

Joins the applied CAN filters such that only CAN frames that match all given CAN filters are passed to user space.

This constant is documented in the Linux documentation.

Availability: Linux >= 4.1.

New in version 3.9.

socket.CAN_ISOTP

CAN_ISOTP, in the CAN protocol family, is the ISO-TP (ISO 15765-2) protocol. ISO-TP constants, documented in the Linux documentation.

Availability: Linux >= 2.6.25.

New in version 3.7.

socket.CAN_J1939

CAN_J1939, in the CAN protocol family, is the SAE J1939 protocol. J1939 constants, documented in the Linux documentation.

Availability: Linux >= 5.4.

New in version 3.9.

socket.AF_PACKET
socket.PF_PACKET
PACKET_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.2.

socket.AF_RDS
socket.PF_RDS
socket.SOL_RDS
RDS_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.30.

New in version 3.3.

socket.SIO_RCVALL
socket.SIO_KEEPALIVE_VALS
socket.SIO_LOOPBACK_FAST_PATH
RCVALL_*

Constants for Windows' WSAIoctl(). The constants are used as arguments to the **`ioctl()`** method of socket objects.

Changed in version 3.6: `SIO_LOOPBACK_FAST_PATH` was added.

TIPC_*

TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

socket.AF_ALG
socket.SOL_ALG
ALG_*

Constants for Linux Kernel cryptography.

Availability: Linux >= 2.6.38.

New in version 3.6.

socket.AF_VSOCK
socket.IOCTL_VM_SOCKETS_GET_LOCAL_CID
VMADDR*
SO_VM*

Constants for Linux host/guest communication.

Availability: Linux >= 4.8.

New in version 3.7.

socket.AF_LINK

Availability: BSD, macOS.

New in version 3.4.

socket.has_ipv6

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

socket.BDADDR_ANY
socket.BDADDR_LOCAL

These are string constants containing Bluetooth addresses with special meanings. For example, **BDADDR_ANY** can be used to indicate any address when specifying the binding socket with **BTPROTO_RFCOMM**.

socket.HCI_FILTER
socket.HCI_TIME_STAMP
socket.HCI_DATA_DIR

For use with **BTPROTO_HCI**. **HCI_FILTER** is not available for NetBSD or DragonFlyBSD. **HCI_TIME_STAMP** and **HCI_DATA_DIR** are not available for FreeBSD, NetBSD, or DragonFlyBSD.

socket.AF_QIPCRTR

Constant for Qualcomm's IPC router protocol, used to communicate with service providing remote processors.

Availability: Linux >= 4.7.

socket.SCM_CREDS2
socket.LOCAL_CREDS
socket.LOCAL_CREDS_PERSISTENT

LOCAL_CREDS and LOCAL_CREDS_PERSISTENT can be used with SOCK_DGRAM, SOCK_STREAM sockets, equivalent to Linux/DragonFlyBSD SO_PASSCRED, while LOCAL_CREDS sends the credentials at first read, LOCAL_CREDS_PERSISTENT sends for each read, SCM_CREDS2 must be then used for the latter for the message type.

New in version 3.11.

Availability: FreeBSD.

socket.SO_INCOMING_CPU

Constant to optimize CPU locality, to be used in conjunction with **`SO_REUSEPORT`**.

New in version 3.11.

Availability: Linux >= 3.9

Functions

Creating sockets

The following functions all create socket objects.

class socket.socket(*family=AF_INET*, *type=SOCK_STREAM*, *proto=0*, *fileno=None*)

Create a new socket using the given address family, socket type and protocol number. The address family should be

AF_INET (the default), **AF_INET6**, **AF_UNIX**, **AF_CAN**, **AF_PACKET**, or **AF_RDS**. The socket type should be **SOCK_STREAM** (the default), **SOCK_DGRAM**, **SOCK_RAW** or perhaps one of the other `SOCK_` constants. The protocol number is usually zero and may be omitted or in the case where the address family is **AF_CAN** the protocol should be one of **CAN_RAW**, **CAN_BCM**, **CAN_ISOTP** or **CAN_J1939**.

If *fileno* is specified, the values for *family*, *type*, and *proto* are auto-detected from the specified file descriptor. Auto-detection can be overruled by calling the function with explicit *family*, *type*, or *proto* arguments. This only affects how Python represents e.g. the return value of **socket.getpeername()** but not the actual OS resource. Unlike **socket.fromfd()**, *fileno* will return the same socket and not a duplicate. This may help close a detached socket using **socket.close()**.

The newly created socket is non-inheritable.

Raises an auditing event `socket.__new__` with arguments `self, family, type, protocol`.

Changed in version 3.3: The AF_CAN family was added. The AF_RDS family was added.

Changed in version 3.4: The CAN_BCM protocol was added.

Changed in version 3.4: The returned socket is now non-inheritable.

Changed in version 3.7: The CAN_ISOTP protocol was added.

Changed in version 3.7: When **SOCK_NONBLOCK** or **SOCK_CLOEXEC** bit flags are applied to *type* they are cleared, and **socket.type** will not reflect them. They are still passed to the underlying system `socket()` call. Therefore,

```
sock = socket.socket(
    socket.AF_INET,
    socket.SOCK_STREAM | socket.SOCK_NONBLOCK)
```

will still create a non-blocking socket on OSes that support `SOCK_NONBLOCK`, but `sock.type` will be set to `socket.SOCK_STREAM`.

Changed in version 3.9: The CAN_J1939 protocol was added.

Changed in version 3.10: The IPPROTO_MPTCP protocol was added.

socket.socketpair([*family*[, *type*[, *proto*]]])

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the **`socket()`** function above. The default family is **`AF_UNIX`** if defined on the platform; otherwise, the default is **`AF_INET`**.

The newly created sockets are non-inheritable.

Changed in version 3.2: The returned socket objects now support the whole socket API, rather than a subset.

Changed in version 3.4: The returned sockets are now non-inheritable.

Changed in version 3.5: Windows support added.

socket.create_connection(*address*, *timeout*=*GLOBAL_DEFAULT*, *source_address*=*None*, *, *all_errors*=*False*)

Connect to a TCP service listening on the internet *address* (a 2-tuple `(host, port)`), and return the socket object. This is a higher-level function than **`socket.connect()`**: if *host* is a non-numeric hostname, it will try to resolve it for both **`AF_INET`** and **`AF_INET6`**, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients that are compatible to both IPv4 and IPv6.

Passing the optional *timeout* parameter will set the timeout on the socket instance before attempting to connect. If no *timeout* is supplied, the global default timeout setting returned by

getdefaulttimeout() is used.

If supplied, *source_address* must be a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting. If host or port are '' or 0 respectively the OS default behavior will be used.

When a connection cannot be created, an exception is raised. By default, it is the exception from the last address in the list. If *all_errors* is `True`, it is an **ExceptionGroup** containing the errors of all attempts.

Changed in version 3.2: source_address was added.

Changed in version 3.11: all_errors was added.

socket.create_server(*address*, *, *family*=*AF_INET*, *backlog*=*None*, *reuse_port*=*False*, *dualstack_ipv6*=*False*)

Convenience function which creates a TCP socket bound to *address* (a 2-tuple `(host, port)`) and return the socket object.

family should be either **AF_INET** or **AF_INET6**. *backlog* is the queue size passed to **socket.listen()**; when `0` a default reasonable value is chosen. *reuse_port* dictates whether to set the **SO_REUSEPORT** socket option.

If *dualstack_ipv6* is true and the platform supports it the socket will be able to accept both IPv4 and IPv6 connections, else it will raise **ValueError**. Most POSIX platforms and Windows are supposed to support this functionality. When this functionality is enabled the address returned by **socket.getpeername()** when an IPv4 connection occurs will be an IPv6 address represented as an IPv4-mapped IPv6 address. If *dualstack_ipv6* is false it will explicitly disable this functionality on platforms that enable it by default (e.g. Linux). This parameter can be used in conjunction with **has_dualstack_ipv6()**:

```
import socket
```

```
addr = ("", 8080)  # all interfaces, port 8080
if socket.has_dualstack_ipv6():
    s = socket.create_server(addr, family=socket.AF
else:
    s = socket.create_server(addr)
```

Note

On POSIX platforms the **SO_REUSEADDR** socket option is set in order to immediately reuse previous sockets which were bound on the same *address* and remained in TIME_WAIT state.

New in version 3.8.

socket.has_dualstack_ipv6()

Return `True` if the platform supports creating a TCP socket which can handle both IPv4 and IPv6 connections.

New in version 3.8.

socket.fromfd(*fd*, *family*, *type*, *proto=0*)

Duplicate the file descriptor *fd* (an integer as returned by a file object's **fileno()** method) and build a socket object from the result. Address family, socket type and protocol number are as for the **socket()** function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode.

The newly created socket is non-inheritable.

Changed in version 3.4: The returned socket is now non-inheritable.

socket.fromshare(*data*)

Instantiate a socket from data obtained from the **`socket.share()`** method. The socket is assumed to be in blocking mode.

Availability: Windows.

New in version 3.3.

socket.SocketType

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

Other functions

The **`socket`** module also offers various network-related services:

socket.close(*fd*)

Close a socket file descriptor. This is like **`os.close()`**, but for sockets. On some platforms (most noticeable Windows) **`os.close()`** does not work for socket file descriptors.

New in version 3.7.

socket.getaddrinfo(*host*, *port*, *family*=*0*, *type*=*0*, *proto*=*0*, *flags*=*0*)

Translate the *host/port* argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. *host* is a domain name, a string representation of an IPv4/v6 address or `None`. *port* is a string service name such as `'http'`, a numeric port number or `None`. By passing `None` as the value of *host* and *port*, you can pass `NULL` to the underlying C API.

The *family*, *type* and *proto* arguments can be optionally specified in order to narrow the list of addresses returned. Passing zero as a value for each of these arguments selects the full range of results. The *flags* argument can be one or several of the `AI_*` constants, and will influence how results are computed and returned. For example, **`AI_NUMERICHOST`**

will disable domain name resolution and will raise an error if *host* is a domain name.

The function returns a list of 5-tuples with the following structure:

```
(family, type, proto, canonname, sockaddr)
```

In these tuples, *family*, *type*, *proto* are all integers and are meant to be passed to the **`socket()`** function. *canonname* will be a string representing the canonical name of the *host* if **`AI_CANONNAME`** is part of the *flags* argument; else *canonname* will be empty. *sockaddr* is a tuple describing a socket address, whose format depends on the returned *family* (a `(address, port)` 2-tuple for **`AF_INET`**, a `(address, port, flowinfo, scope_id)` 4-tuple for **`AF_INET6`**), and is meant to be passed to the **`socket.connect()`** method.

Raises an auditing event `socket.getaddrinfo` with arguments `host`, `port`, `family`, `type`, `protocol`.

The following example fetches address information for a hypothetical TCP connection to `example.org` on port 80 (results may differ on your system if IPv6 isn't enabled):

```
>>> socket.getaddrinfo("example.org", 80, proto=soc
[(socket.AF_INET6, socket.SOCK_STREAM,
 6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80,
 (socket.AF_INET, socket.SOCK_STREAM,
 6, '', ('93.184.216.34', 80))]
```

Changed in version 3.2: parameters can now be passed using keyword arguments.

Changed in version 3.7: for IPv6 multicast addresses, string representing an address will not contain `%scope_id` part.

socket.getfqdn([*name*])

Return a fully qualified domain name for *name*. If *name* is omitted or empty, it is interpreted as the local host. To find

the fully qualified name, the hostname returned by **`gethostbyaddr()`** is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available and *name* was provided, it is returned unchanged. If *name* was empty or equal to `'0.0.0.0'`, the hostname from **`gethostname()`** is returned.

socket.gethostbyname(*hostname*)

Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See **`gethostbyname_ex()`** for a more complete interface. **`gethostbyname()`** does not support IPv6 name resolution, and **`getaddrinfo()`** should be used instead for IPv4/v6 dual stack support.

Raises an auditing event `socket.gethostbyname` with argument `hostname`.

Availability: not WASI.

socket.gethostbyname_ex(*hostname*)

Translate a host name to IPv4 address format, extended interface. Return a triple `(hostname, aliaslist, ipaddrlist)` where *hostname* is the host's primary host name, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). **`gethostbyname_ex()`** does not support IPv6 name resolution, and **`getaddrinfo()`** should be used instead for IPv4/v6 dual stack support.

Raises an auditing event `socket.gethostbyname` with argument `hostname`.

Availability: not WASI.

socket.gethostname()

Return a string containing the hostname of the machine where the Python interpreter is currently executing.

Raises an auditing event `socket.gethostname` with no arguments.

Note: **`gethostname()`** doesn't always return the fully qualified domain name; use **`getfqdn()`** for that.

Availability: not WASI.

socket.gethostbyaddr(*ip_address*)

Return a triple `(hostname, aliaslist, ipaddrlist)` where *hostname* is the primary host name responding to the given *ip_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function **`getfqdn()`**. **`gethostbyaddr()`** supports both IPv4 and IPv6.

Raises an auditing event `socket.gethostbyaddr` with argument `ip_address`.

Availability: not WASI.

socket.getnameinfo(*sockaddr*, *flags*)

Translate a socket address *sockaddr* into a 2-tuple `(host, port)`. Depending on the settings of *flags*, the result can contain a fully qualified domain name or numeric address representation in *host*. Similarly, *port* can contain a string port name or a numeric port number.

For IPv6 addresses, `%scope_id` is appended to the host part if *sockaddr* contains meaningful *scope_id*. Usually this happens for multicast addresses.

For more information about *flags* you can consult *getnameinfo(3)*.

Raises an auditing event `socket.getnameinfo` with argument `sockaddr`.

Availability: not WASI.

socket.getprotobyname(*protocolname*)

Translate an internet protocol name (for example, `'icmp'`) to a constant suitable for passing as the (optional) third argument to the **`socket()`** function. This is usually only needed for sockets opened in "raw" mode (**`SOCK_RAW`**); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

Availability: not WASI.

socket.getservbyname(*servicename*[, *protocolname*])

Translate an internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

Raises an auditing event `socket.getservbyname` with arguments `servicename`, `protocolname`.

Availability: not WASI.

socket.getservbyport(*port*[, *protocolname*])

Translate an internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

Raises an auditing event `socket.getservbyport` with arguments `port`, `protocolname`.

Availability: not WASI.

socket.ntohl(*x*)

Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.ntohs(*x*)

Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

Changed in version 3.10: Raises **OverflowError** if *x* does not fit in a 16-bit unsigned integer.

socket.htonl(*x*)

Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.htons(*x*)

Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

Changed in version 3.10: Raises **OverflowError** if *x* does not fit in a 16-bit unsigned integer.

socket.inet_aton(*ip_string*)

Convert an IPv4 address from dotted-quad string format (for example, '123.45.67.89') to 32-bit packed binary format, as a bytes object four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type **in_addr**, which is the C type for the 32-bit packed binary this function returns.

inet_aton() also accepts strings with less than three dots;

see the Unix manual page *inet(3)* for details.

If the IPv4 address string passed to this function is invalid, **OSError** will be raised. Note that exactly what is valid depends on the underlying C implementation of **inet_aton()**.

inet_aton() does not support IPv6, and **inet_pton()** should be used instead for IPv4/v6 dual stack support.

socket.inet_ntoa(*packed_ip*)

Convert a 32-bit packed IPv4 address (a bytes-like object four bytes in length) to its standard dotted-quad string representation (for example, '123.45.67.89'). This is useful when conversing with a program that uses the standard C library and needs objects of type **in_addr**, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the byte sequence passed to this function is not exactly 4 bytes in length, **OSError** will be raised. **inet_ntoa()** does not support IPv6, and **inet_ntop()** should be used instead for IPv4/v6 dual stack support.

Changed in version 3.5: Writable bytes-like object is now accepted.

socket.inet_pton(*address_family*, *ip_string*)

Convert an IP address from its family-specific string format to a packed, binary format. **inet_pton()** is useful when a library or network protocol calls for an object of type **in_addr** (similar to **inet_aton()**) or **in6_addr**.

Supported values for *address_family* are currently **AF_INET** and **AF_INET6**. If the IP address string *ip_string* is invalid, **OSError** will be raised. Note that exactly what is valid depends on both the value of *address_family* and the underlying implementation of **inet_pton()**.

Availability: Unix, Windows.

Changed in version 3.4: Windows support added

socket.inet_ntop(*address_family*, *packed_ip*)

Convert a packed IP address (a bytes-like object of some number of bytes) to its standard, family-specific string representation (for example, `'7.10.0.5'` or `'5aef:2b::8'`). **inet_ntop()** is useful when a library or network protocol returns an object of type **in_addr** (similar to **inet_ntoa()**) or **in6_addr**.

Supported values for *address_family* are currently **AF_INET** and **AF_INET6**. If the bytes object *packed_ip* is not the correct length for the specified address family, **ValueError** will be raised. **OSError** is raised for errors from the call to **inet_ntop()**.

Availability: Unix, Windows.

Changed in version 3.4: Windows support added

Changed in version 3.5: Writable bytes-like object is now accepted.

socket.CMSG_LEN(*length*)

Return the total length, without trailing padding, of an ancillary data item with associated data of the given *length*. This value can often be used as the buffer size for **recvmsg()** to receive a single item of ancillary data, but **RFC 3542** [https://datatracker.ietf.org/doc/html/rfc3542.html] requires portable applications to use **CMSG_SPACE()** and thus include space for padding, even when the item will be the last in the buffer. Raises **OverflowError** if *length* is outside the permissible range of values.

Availability: Unix, not Emscripten, not WASI.

Most Unix platforms.

New in version 3.3.

socket.CMSG_SPACE(*length*)

Return the buffer size needed for **recvmsg()** to receive an ancillary data item with associated data of the given *length*, along with any trailing padding. The buffer space needed to receive multiple items is the sum of the **CMSG_SPACE()** values for their associated data lengths. Raises **OverflowError** if *length* is outside the permissible range of values.

Note that some systems might support ancillary data without providing this function. Also note that setting the buffer size using the results of this function may not precisely limit the amount of ancillary data that can be received, since additional data may be able to fit into the padding area.

Availability: Unix, not Emscripten, not WASI.

most Unix platforms.

New in version 3.3.

socket.getdefaulttimeout()

Return the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

socket.setdefaulttimeout(*timeout*)

Set the default timeout in seconds (float) for new socket objects. When the socket module is first imported, the default is `None`. See **settimeout()** for possible values and their respective meanings.

socket.sethostname(*name*)

Set the machine's hostname to *name*. This will raise an **OSError** if you don't have enough rights.

Raises an auditing event `socket.sethostname` with

argument `name`.

Availability: Unix.

New in version 3.3.

socket.if_nameindex()

Return a list of network interface information (index int, name string) tuples. **`OSError`** if the system call fails.

Availability: Unix, Windows, not Emscripten, not WASI.

New in version 3.3.

Changed in version 3.8: Windows support was added.

Note

On Windows network interfaces have different names in different contexts (all names are examples):

- UUID: `{FB605B73-AAC2-49A6-9A2F-25416AEA0573}`
- name: `ethernet_32770`
- friendly name: `vEthernet (nat)`
- description: `Hyper-V Virtual Ethernet Adapter`

This function returns names of the second form from the list, `ethernet_32770` in this example case.

socket.if_nametoindex(*if_name*)

Return a network interface index number corresponding to an interface name. **`OSError`** if no interface with the given name exists.

Availability: Unix, Windows, not Emscripten, not WASI.

New in version 3.3.

Changed in version 3.8: Windows support was added.

See also

"Interface name" is a name as documented in **if_nameindex()**.

socket.if_indextoname(*if_index*)

Return a network interface name corresponding to an interface index number. **OSError** if no interface with the given index exists.

Availability: Unix, Windows, not Emscripten, not WASI.

New in version 3.3.

Changed in version 3.8: Windows support was added.

See also

"Interface name" is a name as documented in **if_nameindex()**.

socket.send_fds(*sock*, *buffers*, *fds*[, *flags*[, *address*]])

Send the list of file descriptors *fds* over an **AF_UNIX** socket *sock*. The *fds* parameter is a sequence of file descriptors. Consult **sendmsg()** for the documentation of these parameters.

Availability: Unix, Windows, not Emscripten, not WASI.

Unix platforms supporting **sendmsg()** and **SCM_RIGHTS** mechanism.

New in version 3.9.

socket.recv_fds(*sock*, *bufsize*, *maxfds*[, *flags*])

Receive up to *maxfds* file descriptors from an **AF_UNIX** socket *sock*. Return `(msg, list(fds), flags, addr)`. Consult **recvmsg()** for the documentation of these parameters.

Availability: Unix, Windows, not Emscripten, not WASI.

Unix platforms supporting **sendmsg()** and **SCM_RIGHTS** mechanism.

New in version 3.9.

Note

Any truncated integers at the end of the list of file descriptors.

Socket Objects

Socket objects have the following methods. Except for **makefile()**, these correspond to Unix system calls applicable to sockets.

Changed in version 3.2: Support for the context manager protocol was added. Exiting the context manager is equivalent to calling **close()**.

socket.accept()

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

The newly created socket is non-inheritable.

Changed in version 3.4: The socket is now non-inheritable.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

socket.bind(*address*)

Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — see above.)

Raises an auditing event `socket.bind` with arguments `self, address`.

Availability: not WASI.

socket.close()

Mark the socket closed. The underlying system resource (e.g. a file descriptor) is also closed when all file objects from **makefile()** are closed. Once that happens, all future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed).

Sockets are automatically closed when they are garbage-collected, but it is recommended to **close()** them explicitly, or to use a **with** statement around them.

Changed in version 3.6: **OSError** is now raised if an error occurs when the underlying **close()** call is made.

Note

close() releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call **shutdown()** before **close()**.

socket.connect(*address*)

Connect to a remote socket at *address*. (The format of *address* depends on the address family — see above.)

If the connection is interrupted by a signal, the method waits until the connection completes, or raise a **TimeoutError** on timeout, if the signal handler doesn't raise an exception and the socket is blocking or has a timeout. For non-blocking sockets, the method raises an **InterruptedError** exception if the connection is interrupted by a signal (or the exception raised by the signal handler).

Raises an auditing event `socket.connect` with arguments `self, address`.

Changed in version 3.5: The method now waits until the connection completes instead of raising an **InterruptedError** exception if the connection is interrupted by a signal, the signal handler doesn't raise an exception and the socket is blocking or has a timeout (see the **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

Availability: not WASI.

socket.connect_ex(*address*)

Like `connect(address)`, but return an error indicator instead of raising an exception for errors returned by the C-level **connect()** call (other problems, such as "host not found," can still raise exceptions). The error indicator is `0` if the operation succeeded, otherwise the value of the **errno** variable. This is useful to support, for example, asynchronous connects.

Raises an auditing event `socket.connect` with arguments `self, address`.

Availability: not WASI.

socket.detach()

Put the socket object into closed state without actually closing the underlying file descriptor. The file descriptor is returned, and can be reused for other purposes.

New in version 3.2.

socket.dup()

Duplicate the socket.

The newly created socket is non-inheritable.

Changed in version 3.4: The socket is now non-inheritable.

Availability: not WASI.

socket.fileno()

Return the socket's file descriptor (a small integer), or -1 on failure. This is useful with **`select.select()`**.

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as **`os.fdopen()`**). Unix does not have this limitation.

socket.get_inheritable()

Get the inheritable flag of the socket's file descriptor or socket's handle: `True` if the socket can be inherited in child processes, `False` if it cannot.

New in version 3.4.

socket.getpeername()

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.

socket.getsockname()

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.)

socket.getsockopt(*level*, *optname*[, *buflen*])

Return the value of the given socket option (see the Unix man page *getsockopt(2)*). The needed symbolic constants (**SO_*** etc.) are defined in this module. If *buflen* is absent, an integer option is assumed and its integer value is returned by the function. If *buflen* is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a bytes object. It is up to the caller to decode the contents of the buffer (see the optional built-in module **`struct`** for a way to decode C structures encoded as byte strings).

Availability: not WASI.

socket.getblocking()

Return `True` if socket is in blocking mode, `False` if in non-blocking.

This is equivalent to checking `socket.gettimeout() == 0`.

New in version 3.7.

socket.gettimeout()

Return the timeout in seconds (float) associated with socket operations, or `None` if no timeout is set. This reflects the last call to **`setblocking()`** or **`settimeout()`**.

socket.ioctl(*control*, *option*)

Platform

Windows

The **ioctl()** method is a limited interface to the WSAIoctl system interface. Please refer to the Win32 documentation [https://msdn.microsoft.com/en-us/library/ms741621%28VS.85%29.aspx] for more information.

On other platforms, the generic **fcntl.fcntl()** and **fcntl.ioctl()** functions may be used; they accept a socket object as their first argument.

Currently only the following control codes are supported: `SIO_RCVALL`, `SIO_KEEPALIVE_VALS`, and `SIO_LOOPBACK_FAST_PATH`.

Changed in version 3.6: `SIO_LOOPBACK_FAST_PATH` was added.

socket.listen([*backlog*])

Enable a server to accept connections. If *backlog* is specified, it must be at least 0 (if it is lower, it is set to 0); it specifies the number of unaccepted connections that the system will allow before refusing new connections. If not specified, a default reasonable value is chosen.

Availability: not WASI.

Changed in version 3.5: The *backlog* parameter is now optional.

socket.makefile(*mode*='r', *buffering*=*None*, *, *encoding*=*None*, *errors*=*None*, *newline*=*None*)

Return a file object associated with the socket. The exact returned type depends on the arguments given to **makefile()**. These arguments are interpreted the same way as by the built-in **open()** function, except the only supported *mode* values are `'r'` (default), `'w'` and `'b'`.

The socket must be in blocking mode; it can have a timeout, but the file object's internal buffer may end up in an inconsistent state if a timeout occurs.

Closing the file object returned by **makefile()** won't close

the original socket unless all other file objects have been closed and **`socket.close()`** has been called on the socket object.

Note

On Windows, the file-like object created by **`makefile()`** cannot be used where a file object with a file descriptor is expected, such as the stream arguments of **`subprocess.Popen()`**.

socket.recv(*bufsize*[, *flags*])

Receive data from the socket. The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by *bufsize*. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

Note

For best match with hardware and network realities, the value of *bufsize* should be a relatively small power of 2, for example, 4096.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **`InterruptedError`** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

socket.recvfrom(*bufsize*[, *flags*])

Receive data from the socket. The return value is a pair `(bytes, address)` where *bytes* is a bytes object representing the data received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family —

see above.)

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

Changed in version 3.7: For multicast IPv6 address, first item of *address* does not contain `%scope_id` part anymore. In order to get full IPv6 address use **getnameinfo()**.

socket.recvmsg(*bufsize*[, *ancbufsize*[, *flags*]])

Receive normal data (up to *bufsize* bytes) and ancillary data from the socket. The *ancbufsize* argument sets the size in bytes of the internal buffer used to receive the ancillary data; it defaults to 0, meaning that no ancillary data will be received. Appropriate buffer sizes for ancillary data can be calculated using **CMSG_SPACE()** or **CMSG_LEN()**, and items which do not fit into the buffer might be truncated or discarded. The *flags* argument defaults to 0 and has the same meaning as for **recv()**.

The return value is a 4-tuple: `(data, ancdata, msg_flags, address)`. The *data* item is a **bytes** object holding the non-ancillary data received. The *ancdata* item is a list of zero or more tuples `(cmsg_level, cmsg_type, cmsg_data)` representing the ancillary data (control messages) received: *cmsg_level* and *cmsg_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg_data* is a **bytes** object holding the associated data. The *msg_flags* item is the bitwise OR of various flags indicating conditions on the received message; see your system documentation for details. If the receiving socket is unconnected, *address* is the address of the sending socket, if available; otherwise, its value is unspecified.

On some systems, **sendmsg()** and **recvmsg()** can be used to pass file descriptors between processes over an **AF_UNIX** socket. When this facility is used (it is often restricted to

SOCK_STREAM sockets), **recvmsg()** will return, in its ancillary data, items of the form `(socket.SOL_SOCKET, socket.SCM_RIGHTS, fds)`, where *fds* is a **bytes** object representing the new file descriptors as a binary array of the native C int type. If **recvmsg()** raises an exception after the system call returns, it will first attempt to close any file descriptors received via this mechanism.

Some systems do not indicate the truncated length of ancillary data items which have been only partially received. If an item appears to extend beyond the end of the buffer, **recvmsg()** will issue a **RuntimeWarning**, and will return the part of it which is inside the buffer provided it has not been truncated before the start of its associated data.

On systems which support the **SCM_RIGHTS** mechanism, the following function will receive up to *maxfds* file descriptors, returning the message data and a list containing the descriptors (while ignoring unexpected conditions such as unrelated control messages being received). See also **sendmsg()**.

```
import socket, array

def recv_fds(sock, msglen, maxfds):
    fds = array.array("i")   # Array of ints
    msg, ancdata, flags, addr = sock.recvmsg(msglen
    for cmsg_level, cmsg_type, cmsg_data in ancdata
        if cmsg_level == socket.SOL_SOCKET and cmsg
            # Append data, ignoring any truncated i
            fds.frombytes(cmsg_data[:len(cmsg_data)
    return msg, list(fds)
```

Availability: Unix.

Most Unix platforms.

New in version 3.3.

Changed in version 3.5: If the system call is interrupted and the

signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

socket.recvmsg_into(*buffers*[, *ancbufsize*[, *flags*]])

Receive normal data and ancillary data from the socket, behaving as **recvmsg()** would, but scatter the non-ancillary data into a series of buffers instead of returning a new bytes object. The *buffers* argument must be an iterable of objects that export writable buffers (e.g. **bytearray** objects); these will be filled with successive chunks of the non-ancillary data until it has all been written or there are no more buffers. The operating system may set a limit (**sysconf()** value `SC_IOV_MAX`) on the number of buffers that can be used. The *ancbufsize* and *flags* arguments have the same meaning as for **recvmsg()**.

The return value is a 4-tuple: `(nbytes, ancdata, msg_flags, address)`, where *nbytes* is the total number of bytes of non-ancillary data written into the buffers, and *ancdata*, *msg_flags* and *address* are the same as for **recvmsg()**.

Example:

```
>>> import socket
>>> s1, s2 = socket.socketpair()
>>> b1 = bytearray(b'----')
>>> b2 = bytearray(b'0123456789')
>>> b3 = bytearray(b'--------------')
>>> s1.send(b'Mary had a little lamb')
22
>>> s2.recvmsg_into([b1, memoryview(b2)[2:9], b3])
(22, [], 0, None)
>>> [b1, b2, b3]
[bytearray(b'Mary'), bytearray(b'01 had a 9'), byte
```

Availability: Unix.

Most Unix platforms.

New in version 3.3.

socket.recvfrom_into(*buffer*[, *nbytes*[, *flags*]])

Receive data from the socket, writing it into *buffer* instead of creating a new bytestring. The return value is a pair `(nbytes, address)` where *nbytes* is the number of bytes received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

socket.recv_into(*buffer*[, *nbytes*[, *flags*]])

Receive up to *nbytes* bytes from the socket, storing the data into a buffer rather than creating a new bytestring. If *nbytes* is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

socket.send(*bytes*[, *flags*])

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for **`recv()`** above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this topic, consult the Socket Programming HOWTO.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **`InterruptedError`** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

socket.sendall(*bytes*[, *flags*])

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for **recv()** above. Unlike **send()**, this method continues to send data from *bytes* until either all data has been sent or an error occurs. `None` is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

Changed in version 3.5: The socket timeout is no more reset each time data is sent successfully. The socket timeout is now the maximum total duration to send all data.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

socket.sendto(*bytes*, *address*)

socket.sendto(*bytes*, *flags*, *address*)

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by *address*. The optional *flags* argument has the same meaning as for **recv()** above. Return the number of bytes sent. (The format of *address* depends on the address family — see above.)

Raises an auditing event `socket.sendto` with arguments `self, address`.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

socket.sendmsg(*buffers*[, *ancdata*[, *flags*[, *address*]]])

Send normal and ancillary data to the socket, gathering the

non-ancillary data from a series of buffers and concatenating it into a single message. The *buffers* argument specifies the non-ancillary data as an iterable of bytes-like objects (e.g. **bytes** objects); the operating system may set a limit (**sysconf()** value `SC_IOV_MAX`) on the number of buffers that can be used. The *ancdata* argument specifies the ancillary data (control messages) as an iterable of zero or more tuples `(cmsg_level, cmsg_type, cmsg_data)`, where *cmsg_level* and *cmsg_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg_data* is a bytes-like object holding the associated data. Note that some systems (in particular, systems without **CMSG_SPACE()**) might support sending only one control message per call. The *flags* argument defaults to 0 and has the same meaning as for **send()**. If *address* is supplied and not `None`, it sets a destination address for the message. The return value is the number of bytes of non-ancillary data sent.

The following function sends the list of file descriptors *fds* over an **AF_UNIX** socket, on systems which support the **SCM_RIGHTS** mechanism. See also **recvmsg()**.

```
import socket, array

def send_fds(sock, msg, fds):
    return sock.sendmsg([msg], [(socket.SOL_SOCKET,
```

Availability: Unix, not WASI.

Most Unix platforms.

Raises an auditing event `socket.sendmsg` with arguments `self, address`.

New in version 3.3.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an **InterruptedError** exception (see **PEP 475** [https://

peps.python.org/pep-0475/] for the rationale).

socket.sendmsg_afalg([*msg*,]*, *op*[, *iv*[, *assoclen*[, *flags*]]])

Specialized version of **sendmsg()** for **AF_ALG** socket. Set mode, IV, AEAD associated data length and flags for **AF_ALG** socket.

Availability: Linux >= 2.6.38.

New in version 3.6.

socket.sendfile(*file*, *offset=0*, *count=None*)

Send a file until EOF is reached by using high-performance **os.sendfile** and return the total number of bytes which were sent. *file* must be a regular file object opened in binary mode. If **os.sendfile** is not available (e.g. Windows) or *file* is not a regular file **send()** will be used instead. *offset* tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case **file.tell()** can be used to figure out the number of bytes which were sent. The socket must be of **SOCK_STREAM** type. Non-blocking sockets are not supported.

New in version 3.5.

socket.set_inheritable(*inheritable*)

Set the inheritable flag of the socket's file descriptor or socket's handle.

New in version 3.4.

socket.setblocking(*flag*)

Set blocking or non-blocking mode of the socket: if *flag* is false, the socket is set to non-blocking, else to blocking mode.

This method is a shorthand for certain **settimeout()** calls:

- `sock.setblocking(True)` is equivalent to `sock.settimeout(None)`
- `sock.setblocking(False)` is equivalent to `sock.settimeout(0.0)`

Changed in version 3.7: The method no longer applies **`SOCK_NONBLOCK`** flag on **`socket.type`**.

socket.settimeout(*value*)

Set a timeout on blocking socket operations. The *value* argument can be a nonnegative floating point number expressing seconds, or `None`. If a non-zero value is given, subsequent socket operations will raise a **`timeout`** exception if the timeout period *value* has elapsed before the operation has completed. If zero is given, the socket is put in non-blocking mode. If `None` is given, the socket is put in blocking mode.

For further information, please consult the notes on socket timeouts.

Changed in version 3.7: The method no longer toggles **`SOCK_NONBLOCK`** flag on **`socket.type`**.

socket.setsockopt(*level*, *optname*, *value: int*)

socket.setsockopt(*level*, *optname*, *value: buffer*)

socket.setsockopt(*level*, *optname*, *None*, *optlen: int*)

Set the value of the given socket option (see the Unix manual page *setsockopt(2)*). The needed symbolic constants are defined in the **`socket`** module (**`SO_*`** etc.). The value can be an integer, `None` or a bytes-like object representing a buffer. In the later case it is up to the caller to ensure that the bytestring contains the proper bits (see the optional built-in module **`struct`** for a way to encode C structures as bytestrings). When *value* is set to `None`, *optlen* argument is required. It's equivalent to call **`setsockopt()`** C function with `optval=NULL` and `optlen=optlen`.

Changed in version 3.5: Writable bytes-like object is now accepted.

Changed in version 3.6: setsockopt(level, optname, None, optlen: int) form added.

Availability: not WASI.

socket.shutdown(*how*)

Shut down one or both halves of the connection. If *how* is **SHUT_RD**, further receives are disallowed. If *how* is **SHUT_WR**, further sends are disallowed. If *how* is **SHUT_RDWR**, further sends and receives are disallowed.

Availability: not WASI.

socket.share(*process_id*)

Duplicate a socket and prepare it for sharing with a target process. The target process must be provided with *process_id*. The resulting bytes object can then be passed to the target process using some form of interprocess communication and the socket can be recreated there using **fromshare()**. Once this method has been called, it is safe to close the socket since the operating system has already duplicated it for the target process.

Availability: Windows.

New in version 3.3.

Note that there are no methods **read()** or **write()**; use **recv()** and **send()** without *flags* argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the **socket** constructor.

socket.family

The socket family.

socket.type
: The socket type.

socket.proto
: The socket protocol.

Notes on socket timeouts

A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets are by default always created in blocking mode, but this can be changed by calling `setdefaulttimeout()`.

- In *blocking mode*, operations block until complete or the system returns an error (such as connection timed out).
- In *non-blocking mode*, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately: functions from the `select` can be used to know when and whether a socket is available for reading or writing.
- In *timeout mode*, operations fail if they cannot be completed within the timeout specified for the socket (they raise a `timeout` exception) or if the system returns an error.

Note

At the operating system level, sockets in *timeout mode* are internally set in non-blocking mode. Also, the blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. This implementation detail can have visible consequences if e.g. you decide to use the `fileno()` of a socket.

Timeouts and the `connect` method

The `connect()` operation is also subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling `connect()` or pass a timeout parameter to

`create_connection()`. However, the system network stack may also return a connection timeout error of its own regardless of any Python socket timeout setting.

Timeouts and the `accept` method

If `getdefaulttimeout()` is not `None`, sockets returned by the `accept()` method inherit that timeout. Otherwise, the behaviour depends on settings of the listening socket:

- if the listening socket is in *blocking mode* or in *timeout mode*, the socket returned by `accept()` is in *blocking mode*;
- if the listening socket is in *non-blocking mode*, whether the socket returned by `accept()` is in blocking or non-blocking mode is operating system-dependent. If you want to ensure cross-platform behaviour, it is recommended you manually override this setting.

Example

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence `socket()`, `bind()`, `listen()`, `accept()` (possibly repeating the `accept()` to service more than one client), while a client only needs the sequence `socket()`, `connect()`. Also note that the server does not `sendall()`/`recv()` on the socket it is listening on but on the new socket returned by `accept()`.

The first two examples support IPv4 only.

```
# Echo server program
import socket

HOST = ''                 # Symbolic name meaning all av
PORT = 50007              # Arbitrary non-privileged por
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) a
    s.bind((HOST, PORT))
```

```
    s.listen(1)
    conn, addr = s.accept()
    with conn:
        print('Connected by', addr)
        while True:
            data = conn.recv(1024)
            if not data: break
            conn.sendall(data)

# Echo client program
import socket

HOST = 'daring.cwi.nl'    # The remote host
PORT = 50007              # The same port as used by the
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) a
    s.connect((HOST, PORT))
    s.sendall(b'Hello, world')
    data = s.recv(1024)
print('Received', repr(data))
```

The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

```
# Echo server program
import socket
import sys

HOST = None               # Symbolic name meaning all av
PORT = 50007              # Arbitrary non-privileged por
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSP
                              socket.SOCK_STREAM, 0, soc
    af, socktype, proto, canonname, sa = res
    try:
```

```
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
    try:
        s.bind(sa)
        s.listen(1)
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print('could not open socket')
    sys.exit(1)
conn, addr = s.accept()
with conn:
    print('Connected by', addr)
    while True:
        data = conn.recv(1024)
        if not data: break
        conn.send(data)
```

```
# Echo client program
import socket
import sys

HOST = 'daring.cwi.nl'    # The remote host
PORT = 50007              # The same port as used by the
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSP
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
    try:
        s.connect(sa)
```

```
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print('could not open socket')
    sys.exit(1)
with s:
    s.sendall(b'Hello, world')
    data = s.recv(1024)
print('Received', repr(data))
```

The next example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

```
import socket

# the public network interface
HOST = socket.gethostbyname(socket.gethostname())

# create a raw socket and bind it to the public interfac
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socke
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packets
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a packet
print(s.recvfrom(65565))

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
```

The next example shows how to use the socket interface to

communicate to a CAN network using the raw socket protocol. To use CAN with the broadcast manager protocol instead, open a socket with:

```
socket.socket(socket.AF_CAN, socket.SOCK_DGRAM, socket.C
```

After binding (**CAN_RAW**) or connecting (**CAN_BCM**) the socket, you can use the **socket.send()**, and the **socket.recv()** operations (and their counterparts) on the socket object as usual.

This last example might require special privileges:

```
import socket
import struct

# CAN frame packing/unpacking (see 'struct can_frame' in

can_frame_fmt = "=IB3x8s"
can_frame_size = struct.calcsize(can_frame_fmt)

def build_can_frame(can_id, data):
    can_dlc = len(data)
    data = data.ljust(8, b'\x00')
    return struct.pack(can_frame_fmt, can_id, can_dlc, d

def dissect_can_frame(frame):
    can_id, can_dlc, data = struct.unpack(can_frame_fmt,
    return (can_id, can_dlc, data[:can_dlc])

# create a raw socket and bind it to the 'vcan0' interfa
s = socket.socket(socket.AF_CAN, socket.SOCK_RAW, socket
s.bind(('vcan0',))

while True:
    cf, addr = s.recvfrom(can_frame_size)

    print('Received: can_id=%x, can_dlc=%x, data=%s' % d
```

```
    try:
        s.send(cf)
    except OSError:
        print('Error sending CAN frame')

    try:
        s.send(build_can_frame(0x01, b'\x01\x02\x03'))
    except OSError:
        print('Error sending CAN frame')
```

Running an example several times with too small delay between executions, could lead to this error:

```
OSError: [Errno 98] Address already in use
```

This is because the previous execution has left the socket in a `TIME_WAIT` state, and can't be immediately reused.

There is a **`socket`** flag to set, in order to prevent this, **`socket.SO_REUSEADDR`**:

```
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, 1)
s.bind((HOST, PORT))
```

the **`SO_REUSEADDR`** flag tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire.

For an introduction to socket programming (in C), see the following papers:

- *An Introductory 4.3BSD Interprocess Communication Tutorial*, by Stuart Sechrest
- *An Advanced 4.3BSD Interprocess Communication Tutorial*, by Samuel J. Leffler et al,

both in the UNIX Programmer's Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific

reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to **RFC 3493** [https://datatracker.ietf.org/doc/html/rfc3493.html] titled Basic Socket Interface Extensions for IPv6.

`ssl` — TLS/SSL wrapper for socket objects

Source code: Lib/ssl.py [https://github.com/python/cpython/tree/3.11/Lib/ssl.py]

This module provides access to Transport Layer Security (often known as “Secure Sockets Layer”) encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, macOS, and probably additional platforms, as long as OpenSSL is installed on that platform.

Note

Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior. For example, TLSv1.3 with OpenSSL version 1.1.1.

Warning

Don’t use this module without reading the Security considerations. Doing so may lead to a false sense of security, as the default settings of the ssl module are not necessarily appropriate for your application.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

This section documents the objects and functions in the `ssl` module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the "See Also" section at the bottom.

This module provides a class, **`ssl.SSLSocket`**, which is derived from the **`socket.socket`** type, and provides a socket-like wrapper that also encrypts and decrypts the data going over the socket with SSL. It supports additional methods such as **`getpeercert()`**, which retrieves the certificate of the other side of the connection, and **`cipher()`**, which retrieves the cipher being used for the secure connection.

For more sophisticated applications, the **`ssl.SSLContext`** class helps manage settings and certificates, which can then be inherited by SSL sockets created through the **`SSLContext.wrap_socket()`** method.

Changed in version 3.5.3: Updated to support linking with OpenSSL 1.1.0

Changed in version 3.6: OpenSSL 0.9.8, 1.0.0 and 1.0.1 are deprecated and no longer supported. In the future the ssl module will require at least OpenSSL 1.0.2 or 1.1.0.

Changed in version 3.10: **PEP 644** [https://peps.python.org/pep-0644/] has been implemented. The ssl module requires OpenSSL 1.1.1 or newer.

Use of deprecated constants and functions result in deprecation warnings.

Functions, Constants, and Exceptions

Socket creation

Since Python 3.2 and 2.7.9, it is recommended to use the **`SSLContext.wrap_socket()`** of an **`SSLContext`** instance to wrap sockets as **`SSLSocket`** objects. The helper functions

`create_default_context()` returns a new context with secure default settings. The old **`wrap_socket()`** function is deprecated since it is both inefficient and has no support for server name indication (SNI) and hostname matching.

Client socket example with default context and IPv4/IPv6 dual stack:

```
import socket
import ssl

hostname = 'www.python.org'
context = ssl.create_default_context()

with socket.create_connection((hostname, 443)) as sock:
    with context.wrap_socket(sock, server_hostname=hostr
        print(ssock.version())
```

Client socket example with custom context and IPv4:

```
hostname = 'www.python.org'
# PROTOCOL_TLS_CLIENT requires valid cert chain and host
context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
context.load_verify_locations('path/to/cabundle.pem')

with socket.socket(socket.AF_INET, socket.SOCK_STREAM, 0
    with context.wrap_socket(sock, server_hostname=hostr
        print(ssock.version())
```

Server socket example listening on localhost IPv4:

```
context = ssl.SSLContext(ssl.PROTOCOL_TLS_SERVER)
context.load_cert_chain('/path/to/certchain.pem', '/path

with socket.socket(socket.AF_INET, socket.SOCK_STREAM, 0
    sock.bind(('127.0.0.1', 8443))
    sock.listen(5)
    with context.wrap_socket(sock, server_side=True) as
        conn, addr = ssock.accept()
        ...
```

Context creation

A convenience function helps create **SSLContext** objects for common purposes.

ssl.create_default_context(*purpose*=*Purpose.SERVER_AUTH*, *cafile*=*None*, *capath*=*None*, *cadata*=*None*)

Return a new **SSLContext** object with default settings for the given *purpose*. The settings are chosen by the **ssl** module, and usually represent a higher security level than when calling the **SSLContext** constructor directly.

cafile, *capath*, *cadata* represent optional CA certificates to trust for certificate verification, as in **SSLContext.load_verify_locations()**. If all three are **None**, this function can choose to trust the system's default CA certificates instead.

The settings are: **PROTOCOL_TLS_CLIENT** or **PROTOCOL_TLS_SERVER**, **OP_NO_SSLv2**, and **OP_NO_SSLv3** with high encryption cipher suites without RC4 and without unauthenticated cipher suites. Passing **SERVER_AUTH** as *purpose* sets **verify_mode** to **CERT_REQUIRED** and either loads CA certificates (when at least one of *cafile*, *capath* or *cadata* is given) or uses **SSLContext.load_default_certs()** to load default CA certificates.

When **keylog_filename** is supported and the environment variable **SSLKEYLOGFILE** is set, **create_default_context()** enables key logging.

Note

The protocol, options, cipher and other settings may change to more restrictive values anytime without prior deprecation. The values represent a fair balance between compatibility and security.

If your application needs specific settings, you should

create a **SSLContext** and apply the settings yourself.

Note

If you find that when certain older clients or servers attempt to connect with a **SSLContext** created by this function that they get an error stating "Protocol or cipher suite mismatch", it may be that they only support SSL3.0 which this function excludes using the **OP_NO_SSLv3**. SSL3.0 is widely considered to be completely broken [https://en.wikipedia.org/wiki/POODLE]. If you still wish to continue to use this function but still allow SSL 3.0 connections you can re-enable them using:

```
ctx = ssl.create_default_context(Purpose.CLIENT_AU
ctx.options &= ~ssl.OP_NO_SSLv3
```

New in version 3.4.

Changed in version 3.4.4: RC4 was dropped from the default cipher string.

Changed in version 3.6: ChaCha20/Poly1305 was added to the default cipher string.

3DES was dropped from the default cipher string.

Changed in version 3.8: Support for key logging to **SSLKEYLOGFILE** was added.

Changed in version 3.10: The context now uses **PROTOCOL_TLS_CLIENT** or **PROTOCOL_TLS_SERVER** protocol instead of generic **PROTOCOL_TLS**.

Exceptions

exception ssl.SSLError

Raised to signal an error from the underlying SSL implementation (currently provided by the OpenSSL library). This signifies some problem in the higher-level encryption

and authentication layer that's superimposed on the underlying network connection. This error is a subtype of **OSError**. The error code and message of **SSLError** instances are provided by the OpenSSL library.

Changed in version 3.3: **SSLError** used to be a subtype of **socket.error**.

library

A string mnemonic designating the OpenSSL submodule in which the error occurred, such as `SSL`, `PEM` or `X509`. The range of possible values depends on the OpenSSL version.

New in version 3.3.

reason

A string mnemonic designating the reason this error occurred, for example `CERTIFICATE_VERIFY_FAILED`. The range of possible values depends on the OpenSSL version.

New in version 3.3.

exception ssl.SSLZeroReturnError

A subclass of **SSLError** raised when trying to read or write and the SSL connection has been closed cleanly. Note that this doesn't mean that the underlying transport (read TCP) has been closed.

New in version 3.3.

exception ssl.SSLWantReadError

A subclass of **SSLError** raised by a non-blocking SSL socket when trying to read or write data, but more data needs to be received on the underlying TCP transport before the request can be fulfilled.

New in version 3.3.

exception ssl.SSLWantWriteError

A subclass of **SSLError** raised by a non-blocking SSL socket when trying to read or write data, but more data needs to be sent on the underlying TCP transport before the request can be fulfilled.

New in version 3.3.

exception ssl.SSLSyscallError

A subclass of **SSLError** raised when a system error was encountered while trying to fulfill an operation on a SSL socket. Unfortunately, there is no easy way to inspect the original errno number.

New in version 3.3.

exception ssl.SSLEOFError

A subclass of **SSLError** raised when the SSL connection has been terminated abruptly. Generally, you shouldn't try to reuse the underlying transport when this error is encountered.

New in version 3.3.

exception ssl.SSLCertVerificationError

A subclass of **SSLError** raised when certificate validation has failed.

New in version 3.7.

verify_code

A numeric error number that denotes the verification error.

verify_message

A human readable string of the verification error.

exception ssl.CertificateError

An alias for **SSLCertVerificationError**.

Changed in version 3.7: The exception is now an alias for **SSLCertVerificationError**.

Random generation

ssl.RAND_bytes(*num*)

Return *num* cryptographically strong pseudo-random bytes. Raises an **SSLError** if the PRNG has not been seeded with enough data or if the operation is not supported by the current RAND method. **RAND_status()** can be used to check the status of the PRNG and **RAND_add()** can be used to seed the PRNG.

For almost all applications **os.urandom()** is preferable.

Read the Wikipedia article, Cryptographically secure pseudorandom number generator (CSPRNG) [https://en.wikipedia.org/wiki/Cryptographically_secure_pseudorandom_number_generator], to get the requirements of a cryptographically strong generator.

New in version 3.3.

ssl.RAND_pseudo_bytes(*num*)

Return (bytes, is_cryptographic): bytes are *num* pseudo-random bytes, is_cryptographic is `True` if the bytes generated are cryptographically strong. Raises an **SSLError** if the operation is not supported by the current RAND method.

Generated pseudo-random byte sequences will be unique if they are of sufficient length, but are not necessarily unpredictable. They can be used for non-cryptographic purposes and for certain purposes in cryptographic protocols, but usually not for key generation etc.

For almost all applications **os.urandom()** is preferable.

New in version 3.3.

Deprecated since version 3.6: OpenSSL has deprecated **ssl.RAND_pseudo_bytes()**, use **ssl.RAND_bytes()** instead.

ssl.RAND_status()

Return `True` if the SSL pseudo-random number generator has been seeded with 'enough' randomness, and `False` otherwise. You can use **ssl.RAND_egd()** and **ssl.RAND_add()** to increase the randomness of the pseudo-random number generator.

ssl.RAND_add(*bytes*, *entropy*)

Mix the given *bytes* into the SSL pseudo-random number generator. The parameter *entropy* (a float) is a lower bound on the entropy contained in string (so you can always use **0.0**). See **RFC 1750** [https://datatracker.ietf.org/doc/html/rfc1750.html] for more information on sources of entropy.

Changed in version 3.5: Writable bytes-like object is now accepted.

Certificate handling

ssl.match_hostname(*cert*, *hostname*)

Verify that *cert* (in decoded format as returned by **SSLSocket.getpeercert()**) matches the given *hostname*. The rules applied are those for checking the identity of HTTPS servers as outlined in **RFC 2818** [https://datatracker.ietf.org/doc/html/rfc2818.html], **RFC 5280** [https://datatracker.ietf.org/doc/html/rfc5280.html] and **RFC 6125** [https://datatracker.ietf.org/doc/html/rfc6125.html]. In addition to HTTPS, this function should be suitable for checking the identity of servers in various SSL-based protocols such as FTPS, IMAPS, POPS and others.

CertificateError is raised on failure. On success, the function returns nothing:

```
>>> cert = {'subject': ((('commonName', 'example.co
```

```
>>> ssl.match_hostname(cert, "example.com")
>>> ssl.match_hostname(cert, "example.org")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/py3k/Lib/ssl.py", line 130, in match_
ssl.CertificateError: hostname 'example.org' doesn'
```

New in version 3.2.

Changed in version 3.3.3: The function now follows **RFC 6125** [https://datatracker.ietf.org/doc/html/rfc6125.html], section 6.4.3 and does neither match multiple wildcards (e.g. `*.*.com` or `*a*.example.org`) nor a wildcard inside an internationalized domain names (IDN) fragment. IDN A-labels such as `www*.xn--pthon-kva.org` are still supported, but `x*.python.org` no longer matches `xn--tda.python.org`.

Changed in version 3.5: Matching of IP addresses, when present in the subjectAltName field of the certificate, is now supported.

Changed in version 3.7: The function is no longer used to TLS connections. Hostname matching is now performed by OpenSSL.

Allow wildcard when it is the leftmost and the only character in that segment. Partial wildcards like `www*.example.com` are no longer supported.

Deprecated since version 3.7.

ssl.cert_time_to_seconds(*cert_time*)

Return the time in seconds since the Epoch, given the `cert_time` string representing the “notBefore” or “notAfter” date from a certificate in `"%b %d %H:%M:%S %Y %Z"` strptime format (C locale).

Here’s an example:

```
>>> import ssl
>>> timestamp = ssl.cert_time_to_seconds("Jan  5 09
>>> timestamp
1515144883
>>> from datetime import datetime
>>> print(datetime.utcfromtimestamp(timestamp))
2018-01-05 09:34:43
```

"notBefore" or "notAfter" dates must use GMT (**RFC 5280** [https://datatracker.ietf.org/doc/html/rfc5280.html]).

Changed in version 3.5: Interpret the input time as a time in UTC as specified by 'GMT' timezone in the input string. Local timezone was used previously. Return an integer (no fractions of a second in the input format)

ssl.get_server_certificate(*addr*, *ssl_version*=*PROTOCOL_TLS_CLIENT*, *ca_certs*=*None*[, *timeout*])

Given the address `addr` of an SSL-protected server, as a (*hostname*, *port-number*) pair, fetches the server's certificate, and returns it as a PEM-encoded string. If `ssl_version` is specified, uses that version of the SSL protocol to attempt to connect to the server. If `ca_certs` is specified, it should be a file containing a list of root certificates, the same format as used for the same parameter in **`SSLContext.wrap_socket()`**. The call will attempt to validate the server certificate against that set of root certificates, and will fail if the validation attempt fails. A timeout can be specified with the `timeout` parameter.

Changed in version 3.3: This function is now IPv6-compatible.

Changed in version 3.5: The default *ssl_version* is changed from **`PROTOCOL_SSLv3`** to **`PROTOCOL_TLS`** for maximum compatibility with modern servers.

Changed in version 3.10: The *timeout* parameter was added.

ssl.DER_cert_to_PEM_cert(*DER_cert_bytes*)

Given a certificate as a DER-encoded blob of bytes, returns a PEM-encoded string version of the same certificate.

ssl.PEM_cert_to_DER_cert(*PEM_cert_string*)

Given a certificate as an ASCII PEM string, returns a DER-encoded sequence of bytes for that same certificate.

ssl.get_default_verify_paths()

Returns a named tuple with paths to OpenSSL's default cafile and capath. The paths are the same as used by **`SSLContext.set_default_verify_paths()`**. The return value is a named tuple `DefaultVerifyPaths`:

- **`cafile`** - resolved path to cafile or `None` if the file doesn't exist,
- **`capath`** - resolved path to capath or `None` if the directory doesn't exist,
- **`openssl_cafile_env`** - OpenSSL's environment key that points to a cafile,
- **`openssl_cafile`** - hard coded path to a cafile,
- **`openssl_capath_env`** - OpenSSL's environment key that points to a capath,
- **`openssl_capath`** - hard coded path to a capath directory

New in version 3.4.

ssl.enum_certificates(*store_name*)

Retrieve certificates from Windows' system cert store. *store_name* may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The encoding_type specifies the encoding of cert_bytes. It is either **`x509_asn`** for X.509 ASN.1 data or **`pkcs_7_asn`** for PKCS#7 ASN.1 data. Trust specifies the purpose of the certificate as a set of OIDS or exactly `True` if the certificate is trustworthy for all purposes.

Example:

```
>>> ssl.enum_certificates("CA")
[(b'data...', 'x509_asn', {'1.3.6.1.5.5.7.3.1', '1.
 (b'data...', 'x509_asn', True)]
```

Availability: Windows.

New in version 3.4.

ssl.enum_crls(*store_name*)

Retrieve CRLs from Windows' system cert store. *store_name* may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The encoding_type specifies the encoding of cert_bytes. It is either **`x509_asn`** for X.509 ASN.1 data or **`pkcs_7_asn`** for PKCS#7 ASN.1 data.

Availability: Windows.

New in version 3.4.

ssl.wrap_socket(*sock*, *keyfile=None*, *certfile=None*, *server_side=False*, *cert_reqs=CERT_NONE*, *ssl_version=PROTOCOL_TLS*, *ca_certs=None*, *do_handshake_on_connect=True*, *suppress_ragged_eofs=True*, *ciphers=None*)

Takes an instance `sock` of **`socket.socket`**, and returns an instance of **`ssl.SSLSocket`**, a subtype of **`socket.socket`**, which wraps the underlying socket in an SSL context. `sock` must be a **`SOCK_STREAM`** socket; other socket types are unsupported.

Internally, function creates a **`SSLContext`** with protocol *ssl_version* and **`SSLContext.options`** set to *cert_reqs*. If parameters *keyfile*, *certfile*, *ca_certs* or *ciphers* are set, then the values are passed to **`SSLContext.load_cert_chain()`**, **`SSLContext.load_verify_locations()`**, and **`SSLContext.set_ciphers()`**.

The arguments *server_side*, *do_handshake_on_connect*, and *suppress_ragged_eofs* have the same meaning as **SSLContext.wrap_socket()**.

Deprecated since version 3.7: Since Python 3.2 and 2.7.9, it is recommended to use the **SSLContext.wrap_socket()** instead of **wrap_socket()**. The top-level function is limited and creates an insecure client socket without server name indication or hostname matching.

Constants

All constants are now **enum.IntEnum** or **enum.IntFlag** collections.

New in version 3.6.

ssl.CERT_NONE

Possible value for **SSLContext.verify_mode**, or the `cert_reqs` parameter to **wrap_socket()**. Except for **PROTOCOL_TLS_CLIENT**, it is the default mode. With client-side sockets, just about any cert is accepted. Validation errors, such as untrusted or expired cert, are ignored and do not abort the TLS/SSL handshake.

In server mode, no certificate is requested from the client, so the client does not send any for client cert authentication.

See the discussion of Security considerations below.

ssl.CERT_OPTIONAL

Possible value for **SSLContext.verify_mode**, or the `cert_reqs` parameter to **wrap_socket()**. In client mode, **CERT_OPTIONAL** has the same meaning as **CERT_REQUIRED**. It is recommended to use **CERT_REQUIRED** for client-side sockets instead.

In server mode, a client certificate request is sent to the client. The client may either ignore the request or send a certificate in order perform TLS client cert authentication. If

the client chooses to send a certificate, it is verified. Any verification error immediately aborts the TLS handshake.

Use of this setting requires a valid set of CA certificates to be passed, either to **SSLContext.load_verify_locations()** or as a value of the `ca_certs` parameter to **wrap_socket()**.

ssl.CERT_REQUIRED

Possible value for **SSLContext.verify_mode**, or the `cert_reqs` parameter to **wrap_socket()**. In this mode, certificates are required from the other side of the socket connection; an **SSLError** will be raised if no certificate is provided, or if its validation fails. This mode is **not** sufficient to verify a certificate in client mode as it does not match hostnames. **check_hostname** must be enabled as well to verify the authenticity of a cert. **PROTOCOL_TLS_CLIENT** uses **CERT_REQUIRED** and enables **check_hostname** by default.

With server socket, this mode provides mandatory TLS client cert authentication. A client certificate request is sent to the client and the client must provide a valid and trusted certificate.

Use of this setting requires a valid set of CA certificates to be passed, either to **SSLContext.load_verify_locations()** or as a value of the `ca_certs` parameter to **wrap_socket()**.

class ssl.VerifyMode

enum.IntEnum collection of CERT_* constants.

New in version 3.6.

ssl.VERIFY_DEFAULT

Possible value for **SSLContext.verify_flags**. In this mode, certificate revocation lists (CRLs) are not checked. By default OpenSSL does neither require nor verify CRLs.

New in version 3.4.

ssl.VERIFY_CRL_CHECK_LEAF

Possible value for **SSLContext.verify_flags**. In this mode, only the peer cert is checked but none of the intermediate CA certificates. The mode requires a valid CRL that is signed by the peer cert's issuer (its direct ancestor CA). If no proper CRL has been loaded with **SSLContext.load_verify_locations**, validation will fail.

New in version 3.4.

ssl.VERIFY_CRL_CHECK_CHAIN

Possible value for **SSLContext.verify_flags**. In this mode, CRLs of all certificates in the peer cert chain are checked.

New in version 3.4.

ssl.VERIFY_X509_STRICT

Possible value for **SSLContext.verify_flags** to disable workarounds for broken X.509 certificates.

New in version 3.4.

ssl.VERIFY_ALLOW_PROXY_CERTS

Possible value for **SSLContext.verify_flags** to enables proxy certificate verification.

New in version 3.10.

ssl.VERIFY_X509_TRUSTED_FIRST

Possible value for **SSLContext.verify_flags**. It instructs OpenSSL to prefer trusted certificates when building the trust chain to validate a certificate. This flag is enabled by default.

New in version 3.4.4.

ssl.VERIFY_X509_PARTIAL_CHAIN

Possible value for **SSLContext.verify_flags**. It instructs OpenSSL to accept intermediate CAs in the trust store to be treated as trust-anchors, in the same way as the self-signed root CA certificates. This makes it possible to trust certificates issued by an intermediate CA without having to trust its ancestor root CA.

New in version 3.10.

class ssl.VerifyFlags

enum.IntFlag collection of VERIFY_* constants.

New in version 3.6.

ssl.PROTOCOL_TLS

Selects the highest protocol version that both the client and server support. Despite the name, this option can select both "SSL" and "TLS" protocols.

New in version 3.6.

Deprecated since version 3.10: TLS clients and servers require different default settings for secure communication. The generic TLS protocol constant is deprecated in favor of **PROTOCOL_TLS_CLIENT** and **PROTOCOL_TLS_SERVER**.

ssl.PROTOCOL_TLS_CLIENT

Auto-negotiate the highest protocol version that both the client and server support, and configure the context client-side connections. The protocol enables **CERT_REQUIRED** and **check_hostname** by default.

New in version 3.6.

ssl.PROTOCOL_TLS_SERVER

Auto-negotiate the highest protocol version that both the client and server support, and configure the context server-side connections.

New in version 3.6.

ssl.PROTOCOL_SSLv23

Alias for **PROTOCOL_TLS**.

Deprecated since version 3.6: Use **PROTOCOL_TLS** instead.

ssl.PROTOCOL_SSLv2

Selects SSL version 2 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with the `no-ssl2` option.

Warning

SSL version 2 is insecure. Its use is highly discouraged.

Deprecated since version 3.6: OpenSSL has removed support for SSLv2.

ssl.PROTOCOL_SSLv3

Selects SSL version 3 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with the `no-ssl3` option.

Warning

SSL version 3 is insecure. Its use is highly discouraged.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol **PROTOCOL_TLS_SERVER** or **PROTOCOL_TLS_CLIENT** with **SSLContext.minimum_version** and **SSLContext.maximum_version** instead.

ssl.PROTOCOL_TLSv1

Selects TLS version 1.0 as the channel encryption protocol.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols.

ssl.PROTOCOL_TLSv1_1

Selects TLS version 1.1 as the channel encryption protocol. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols.

ssl.PROTOCOL_TLSv1_2

Selects TLS version 1.2 as the channel encryption protocol. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols.

ssl.OP_ALL

Enables workarounds for various bugs present in other SSL implementations. This option is set by default. It does not necessarily set the same flags as OpenSSL's `SSL_OP_ALL` constant.

New in version 3.2.

ssl.OP_NO_SSLv2

Prevents an SSLv2 connection. This option is only applicable in conjunction with **`PROTOCOL_TLS`**. It prevents the peers from choosing SSLv2 as the protocol version.

New in version 3.2.

Deprecated since version 3.6: SSLv2 is deprecated

ssl.OP_NO_SSLv3

Prevents an SSLv3 connection. This option is only applicable in conjunction with **PROTOCOL_TLS**. It prevents the peers from choosing SSLv3 as the protocol version.

New in version 3.2.

Deprecated since version 3.6: SSLv3 is deprecated

ssl.OP_NO_TLSv1

Prevents a TLSv1 connection. This option is only applicable in conjunction with **PROTOCOL_TLS**. It prevents the peers from choosing TLSv1 as the protocol version.

New in version 3.2.

Deprecated since version 3.7: The option is deprecated since OpenSSL 1.1.0, use the new **SSLContext.minimum_version** and **SSLContext.maximum_version** instead.

ssl.OP_NO_TLSv1_1

Prevents a TLSv1.1 connection. This option is only applicable in conjunction with **PROTOCOL_TLS**. It prevents the peers from choosing TLSv1.1 as the protocol version. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.7: The option is deprecated since OpenSSL 1.1.0.

ssl.OP_NO_TLSv1_2

Prevents a TLSv1.2 connection. This option is only applicable in conjunction with **PROTOCOL_TLS**. It prevents the peers from choosing TLSv1.2 as the protocol version. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.7: The option is deprecated since

OpenSSL 1.1.0.

ssl.OP_NO_TLSv1_3

Prevents a TLSv1.3 connection. This option is only applicable in conjunction with **PROTOCOL_TLS**. It prevents the peers from choosing TLSv1.3 as the protocol version. TLS 1.3 is available with OpenSSL 1.1.1 or later. When Python has been compiled against an older version of OpenSSL, the flag defaults to *0*.

New in version 3.7.

Deprecated since version 3.7: The option is deprecated since OpenSSL 1.1.0. It was added to 2.7.15, 3.6.3 and 3.7.0 for backwards compatibility with OpenSSL 1.0.2.

ssl.OP_NO_RENEGOTIATION

Disable all renegotiation in TLSv1.2 and earlier. Do not send HelloRequest messages, and ignore renegotiation requests via ClientHello.

This option is only available with OpenSSL 1.1.0h and later.

New in version 3.7.

ssl.OP_CIPHER_SERVER_PREFERENCE

Use the server's cipher ordering preference, rather than the client's. This option has no effect on client sockets and SSLv2 server sockets.

New in version 3.3.

ssl.OP_SINGLE_DH_USE

Prevents re-use of the same DH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

New in version 3.3.

ssl.OP_SINGLE_ECDH_USE

Prevents re-use of the same ECDH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

New in version 3.3.

ssl.OP_ENABLE_MIDDLEBOX_COMPAT

Send dummy Change Cipher Spec (CCS) messages in TLS 1.3 handshake to make a TLS 1.3 connection look more like a TLS 1.2 connection.

This option is only available with OpenSSL 1.1.1 and later.

New in version 3.8.

ssl.OP_NO_COMPRESSION

Disable compression on the SSL channel. This is useful if the application protocol supports its own compression scheme.

New in version 3.3.

class ssl.Options

enum.IntFlag collection of OP_* constants.

ssl.OP_NO_TICKET

Prevent client side from requesting a session ticket.

New in version 3.6.

ssl.OP_IGNORE_UNEXPECTED_EOF

Ignore unexpected shutdown of TLS connections.

This option is only available with OpenSSL 3.0.0 and later.

New in version 3.10.

ssl.HAS_ALPN

Whether the OpenSSL library has built-in support for the *Application-Layer Protocol Negotiation* TLS extension as described in **RFC 7301** [https://datatracker.ietf.org/doc/html/rfc7301.html].

New in version 3.5.

ssl.HAS_NEVER_CHECK_COMMON_NAME

Whether the OpenSSL library has built-in support not checking subject common name and **`SSLContext.hostname_checks_common_name`** is writeable.

New in version 3.7.

ssl.HAS_ECDH

Whether the OpenSSL library has built-in support for the Elliptic Curve-based Diffie-Hellman key exchange. This should be true unless the feature was explicitly disabled by the distributor.

New in version 3.3.

ssl.HAS_SNI

Whether the OpenSSL library has built-in support for the *Server Name Indication* extension (as defined in **RFC 6066** [https://datatracker.ietf.org/doc/html/rfc6066.html]).

New in version 3.2.

ssl.HAS_NPN

Whether the OpenSSL library has built-in support for the *Next Protocol Negotiation* as described in the Application Layer Protocol Negotiation [https://en.wikipedia.org/wiki/Application-Layer_Protocol_Negotiation]. When true, you can use the **`SSLContext.set_npn_protocols()`** method to advertise which protocols you want to support.

New in version 3.3.

ssl.HAS_SSLv2

Whether the OpenSSL library has built-in support for the SSL 2.0 protocol.

New in version 3.7.

ssl.HAS_SSLv3

Whether the OpenSSL library has built-in support for the SSL 3.0 protocol.

New in version 3.7.

ssl.HAS_TLSv1

Whether the OpenSSL library has built-in support for the TLS 1.0 protocol.

New in version 3.7.

ssl.HAS_TLSv1_1

Whether the OpenSSL library has built-in support for the TLS 1.1 protocol.

New in version 3.7.

ssl.HAS_TLSv1_2

Whether the OpenSSL library has built-in support for the TLS 1.2 protocol.

New in version 3.7.

ssl.HAS_TLSv1_3

Whether the OpenSSL library has built-in support for the TLS 1.3 protocol.

New in version 3.7.

ssl.CHANNEL_BINDING_TYPES

List of supported TLS channel binding types. Strings in this list can be used as arguments to

SSLSocket.get_channel_binding().

New in version 3.3.

ssl.OPENSSL_VERSION

The version string of the OpenSSL library loaded by the interpreter:

```
>>> ssl.OPENSSL_VERSION
'OpenSSL 1.0.2k  26 Jan 2017'
```

New in version 3.2.

ssl.OPENSSL_VERSION_INFO

A tuple of five integers representing version information about the OpenSSL library:

```
>>> ssl.OPENSSL_VERSION_INFO
(1, 0, 2, 11, 15)
```

New in version 3.2.

ssl.OPENSSL_VERSION_NUMBER

The raw version number of the OpenSSL library, as a single integer:

```
>>> ssl.OPENSSL_VERSION_NUMBER
268443839
>>> hex(ssl.OPENSSL_VERSION_NUMBER)
'0x100020bf'
```

New in version 3.2.

ssl.ALERT_DESCRIPTION_HANDSHAKE_FAILURE
ssl.ALERT_DESCRIPTION_INTERNAL_ERROR
ALERT_DESCRIPTION_*

Alert Descriptions from **RFC 5246** [https://datatracker.ietf.org/doc/html/rfc5246.html] and others. The IANA TLS Alert Registry [https://www.iana.org/assignments/tls-parameters/tls-parameters.xml#tls-parameters-6] contains this list and references to the RFCs

where their meaning is defined.

Used as the return value of the callback function in **SSLContext.set_servername_callback()**.

New in version 3.4.

class ssl.AlertDescription

enum.IntEnum collection of ALERT_DESCRIPTION_* constants.

New in version 3.6.

Purpose.SERVER_AUTH

Option for **create_default_context()** and **SSLContext.load_default_certs()**. This value indicates that the context may be used to authenticate web servers (therefore, it will be used to create client-side sockets).

New in version 3.4.

Purpose.CLIENT_AUTH

Option for **create_default_context()** and **SSLContext.load_default_certs()**. This value indicates that the context may be used to authenticate web clients (therefore, it will be used to create server-side sockets).

New in version 3.4.

class ssl.SSLErrorNumber

enum.IntEnum collection of SSL_ERROR_* constants.

New in version 3.6.

class ssl.TLSVersion

enum.IntEnum collection of SSL and TLS versions for **SSLContext.maximum_version** and

SSLContext.minimum_version.

New in version 3.7.

TLSVersion.MINIMUM_SUPPORTED

TLSVersion.MAXIMUM_SUPPORTED

The minimum or maximum supported SSL or TLS version. These are magic constants. Their values don't reflect the lowest and highest available TLS/SSL versions.

TLSVersion.SSLv3

TLSVersion.TLSv1

TLSVersion.TLSv1_1

TLSVersion.TLSv1_2

TLSVersion.TLSv1_3

SSL 3.0 to TLS 1.3.

Deprecated since version 3.10: All **TLSVersion** members except **TLSVersion.TLSv1_2** and **TLSVersion.TLSv1_3** are deprecated.

SSL Sockets

class ssl.SSLSocket(*socket.socket*)

SSL sockets provide the following methods of Socket Objects:

- **accept()**
- **bind()**
- **close()**
- **connect()**
- **detach()**
- **fileno()**
- **getpeername()**, **getsockname()**

- **getsockopt()**, **setsockopt()**
- **gettimeout()**, **settimeout()**, **setblocking()**
- **listen()**
- **makefile()**
- **recv()**, **recv_into()** (but passing a non-zero `flags` argument is not allowed)
- **send()**, **sendall()** (with the same limitation)
- **sendfile()** (but **os.sendfile** will be used for plain-text sockets only, else **send()** will be used)
- **shutdown()**

However, since the SSL (and TLS) protocol has its own framing atop of TCP, the SSL sockets abstraction can, in certain respects, diverge from the specification of normal, OS-level sockets. See especially the notes on non-blocking sockets.

Instances of **SSLSocket** must be created using the **SSLContext.wrap_socket()** method.

Changed in version 3.5: The **sendfile()** method was added.

Changed in version 3.5: The **shutdown()** does not reset the socket timeout each time bytes are received or sent. The socket timeout is now to maximum total duration of the shutdown.

Deprecated since version 3.6: It is deprecated to create a **SSLSocket** instance directly, use **SSLContext.wrap_socket()** to wrap a socket.

Changed in version 3.7: **SSLSocket** instances must to created with **wrap_socket()**. In earlier versions, it was possible to create instances directly. This was never documented or officially supported.

Changed in version 3.10: Python now uses `SSL_read_ex` and `SSL_write_ex` internally. The functions support reading and writing of data larger than 2 GB. Writing zero-length data no longer fails with a protocol violation error.

SSL sockets also have the following additional methods and attributes:

SSLSocket.read(*len=1024*, *buffer=None*)

Read up to *len* bytes of data from the SSL socket and return the result as a `bytes` instance. If *buffer* is specified, then read into the buffer instead, and return the number of bytes read.

Raise **SSLWantReadError** or **SSLWantWriteError** if the socket is non-blocking and the read would block.

As at any time a re-negotiation is possible, a call to **read()** can also cause write operations.

Changed in version 3.5: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to read up to *len* bytes.

Deprecated since version 3.6: Use **recv()** instead of **read()**.

SSLSocket.write(*buf*)

Write *buf* to the SSL socket and return the number of bytes written. The *buf* argument must be an object supporting the buffer interface.

Raise **SSLWantReadError** or **SSLWantWriteError** if the socket is non-blocking and the write would block.

As at any time a re-negotiation is possible, a call to **write()** can also cause read operations.

Changed in version 3.5: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to write *buf*.

Deprecated since version 3.6: Use **send()** instead of **write()**.

Note

The **read()** and **write()** methods are the low-level methods that read and write unencrypted, application-level data and decrypt/encrypt it to encrypted, wire-level data. These methods require an active SSL connection, i.e. the handshake was completed and **SSLSocket.unwrap()** was not called.

Normally you should use the socket API methods like **recv()** and **send()** instead of these methods.

SSLSocket.do_handshake()

Perform the SSL setup handshake.

Changed in version 3.4: The handshake method also performs **match_hostname()** when the **check_hostname** attribute of the socket's **context** is true.

Changed in version 3.5: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration of the handshake.

Changed in version 3.7: Hostname or IP address is matched by OpenSSL during handshake. The function **match_hostname()** is no longer used. In case OpenSSL refuses a hostname or IP address, the handshake is aborted early and a TLS alert message is send to the peer.

SSLSocket.getpeercert(*binary_form=False*)

If there is no certificate for the peer on the other end of the connection, return `None`. If the SSL handshake hasn't been done yet, raise **ValueError**.

If the `binary_form` parameter is **False**, and a certificate was received from the peer, this method returns a **dict** instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with several keys, amongst them `subject` (the principal for which the certificate was issued) and `issuer` (the principal issuing the certificate). If a certificate contains an instance of the *Subject Alternative Name* extension (see **RFC 3280** [https://

datatracker.ietf.org/doc/html/rfc3280.html]), there will also be a `subjectAltName` key in the dictionary.

The `subject` and `issuer` fields are tuples containing the sequence of relative distinguished names (RDNs) given in the certificate's data structure for the respective fields, and each RDN is a sequence of name-value pairs. Here is a real-world example:

```
{'issuer': ((('countryName', 'IL'),),
            (('organizationName', 'StartCom Ltd.'),
            (('organizationalUnitName',
              'Secure Digital Certificate Signing')
            (('commonName',
              'StartCom Class 2 Primary Intermediat
 'notAfter': 'Nov 22 08:15:19 2013 GMT',
 'notBefore': 'Nov 21 03:09:52 2011 GMT',
 'serialNumber': '95F0',
 'subject': ((('description', '571208-SLe257oHY9fVQ
             (('countryName', 'US'),),
             (('stateOrProvinceName', 'California')
             (('localityName', 'San Francisco'),),
             (('organizationName', 'Electronic Fron
             (('commonName', '*.eff.org'),),
             (('emailAddress', 'hostmaster@eff.org'
 'subjectAltName': (('DNS', '*.eff.org'), ('DNS', '
 'version': 3}
```

Note

To validate a certificate for a particular service, you can use the **`match_hostname()`** function.

If the `binary_form` parameter is **`True`**, and a certificate was provided, this method returns the DER-encoded form of the entire certificate as a sequence of bytes, or **`None`** if the peer did not provide a certificate. Whether the peer provides a certificate depends on the SSL socket's role:

- for a client SSL socket, the server will always provide a

certificate, regardless of whether validation was required;

- for a server SSL socket, the client will only provide a certificate when requested by the server; therefore **`getpeercert()`** will return **`None`** if you used **`CERT_NONE`** (rather than **`CERT_OPTIONAL`** or **`CERT_REQUIRED`**).

Changed in version 3.2: The returned dictionary includes additional items such as `issuer` and `notBefore`.

Changed in version 3.4: **`ValueError`** is raised when the handshake isn't done. The returned dictionary includes additional X509v3 extension items such as `crlDistributionPoints`, `caIssuers` and `OCSP` URIs.

Changed in version 3.9: IPv6 address strings no longer have a trailing new line.

SSLSocket.cipher()

Returns a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns `None`.

SSLSocket.shared_ciphers()

Return the list of ciphers shared by the client during the handshake. Each entry of the returned list is a three-value tuple containing the name of the cipher, the version of the SSL protocol that defines its use, and the number of secret bits the cipher uses. **`shared_ciphers()`** returns `None` if no connection has been established or the socket is a client socket.

New in version 3.5.

SSLSocket.compression()

Return the compression algorithm being used as a string, or `None` if the connection isn't compressed.

If the higher-level protocol supports its own compression mechanism, you can use **OP_NO_COMPRESSION** to disable SSL-level compression.

New in version 3.3.

SSLSocket.get_channel_binding(*cb_type='tls-unique'*)

Get channel binding data for current connection, as a bytes object. Returns `None` if not connected or the handshake has not been completed.

The *cb_type* parameter allow selection of the desired channel binding type. Valid channel binding types are listed in the **CHANNEL_BINDING_TYPES** list. Currently only the 'tls-unique' channel binding, defined by **RFC 5929** [https://datatracker.ietf.org/doc/html/rfc5929.html], is supported. **ValueError** will be raised if an unsupported channel binding type is requested.

New in version 3.3.

SSLSocket.selected_alpn_protocol()

Return the protocol that was selected during the TLS handshake. If **SSLContext.set_alpn_protocols()** was not called, if the other party does not support ALPN, if this socket does not support any of the client's proposed protocols, or if the handshake has not happened yet, `None` is returned.

New in version 3.5.

SSLSocket.selected_npn_protocol()

Return the higher-level protocol that was selected during the TLS/SSL handshake. If **SSLContext.set_npn_protocols()** was not called, or if the other party does not support NPN, or if the handshake has not yet happened, this will return `None`.

New in version 3.3.

Deprecated since version 3.10: NPN has been superseded by ALPN

SSLSocket.unwrap()

Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The returned socket should always be used for further communication with the other side of the connection, rather than the original socket.

SSLSocket.verify_client_post_handshake()

Requests post-handshake authentication (PHA) from a TLS 1.3 client. PHA can only be initiated for a TLS 1.3 connection from a server-side socket, after the initial TLS handshake and with PHA enabled on both sides, see **`SSLContext.post_handshake_auth`**.

The method does not perform a cert exchange immediately. The server-side sends a CertificateRequest during the next write event and expects the client to respond with a certificate on the next read event.

If any precondition isn't met (e.g. not TLS 1.3, PHA not enabled), an **`SSLError`** is raised.

Note

Only available with OpenSSL 1.1.1 and TLS 1.3 enabled. Without TLS 1.3 support, the method raises **`NotImplementedError`**.

New in version 3.8.

SSLSocket.version()

Return the actual SSL protocol version negotiated by the connection as a string, or `None` if no secure connection is

established. As of this writing, possible return values include `"SSLv2"`, `"SSLv3"`, `"TLSv1"`, `"TLSv1.1"` and `"TLSv1.2"`. Recent OpenSSL versions may define more return values.

New in version 3.5.

SSLSocket.pending()

Returns the number of already decrypted bytes available for read, pending on the connection.

SSLSocket.context

The **`SSLContext`** object this SSL socket is tied to. If the SSL socket was created using the deprecated **`wrap_socket()`** function (rather than **`SSLContext.wrap_socket()`**), this is a custom context object created for this SSL socket.

New in version 3.2.

SSLSocket.server_side

A boolean which is `True` for server-side sockets and `False` for client-side sockets.

New in version 3.2.

SSLSocket.server_hostname

Hostname of the server: **`str`** type, or `None` for server-side socket or if the hostname was not specified in the constructor.

New in version 3.2.

Changed in version 3.7: The attribute is now always ASCII text. When `server_hostname` is an internationalized domain name (IDN), this attribute now stores the A-label form (`"xn--pythn-mua.org"`), rather than the U-label form (`"pythön.org"`).

SSLSocket.session

The **`SSLSession`** for this SSL connection. The session is

available for client and server side sockets after the TLS handshake has been performed. For client sockets the session can be set before `do_handshake()` has been called to reuse a session.

New in version 3.6.

SSLSocket.session_reused

New in version 3.6.

SSL Contexts

New in version 3.2.

An SSL context holds various data longer-lived than single SSL connections, such as SSL configuration options, certificate(s) and private key(s). It also manages a cache of SSL sessions for server-side sockets, in order to speed up repeated connections from the same clients.

class ssl.SSLContext(*protocol=None*)

Create a new SSL context. You may pass *protocol* which must be one of the `PROTOCOL_*` constants defined in this module. The parameter specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server's choice. Most of the versions are not interoperable with the other versions. If not specified, the default is `PROTOCOL_TLS`; it provides the most compatibility with other versions.

Here's a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

yes	*TLSv1.1*
yes	*TLSv1.2*

Footnotes

1(*1*,*2*)

SSLContext disables SSLv2 with **OP_NO_SSLv2** by default.

2(*1*,*2*)

SSLContext disables SSLv3 with **OP_NO_SSLv3** by default.

3(*1*,*2*)

TLS 1.3 protocol will be available with **PROTOCOL_TLS** in OpenSSL >= 1.1.1. There is no dedicated PROTOCOL constant for just TLS 1.3.

See also

create_default_context() lets the **ssl** module choose security settings for a given purpose.

Changed in version 3.6: The context is created with secure default values. The options **OP_NO_COMPRESSION**, **OP_CIPHER_SERVER_PREFERENCE**, **OP_SINGLE_DH_USE**, **OP_SINGLE_ECDH_USE**, **OP_NO_SSLv2** (except for **PROTOCOL_SSLv2**), and **OP_NO_SSLv3** (except for **PROTOCOL_SSLv3**) are set by default. The initial cipher suite list contains only `HIGH` ciphers, no `NULL` ciphers and no `MD5` ciphers (except for **PROTOCOL_SSLv2**).

Deprecated since version 3.10: **SSLContext** without protocol argument is deprecated. The context class will either require **PROTOCOL_TLS_CLIENT** or **PROTOCOL_TLS_SERVER** protocol in the future.

Changed in version 3.10: The default cipher suites now include

only secure AES and ChaCha20 ciphers with forward secrecy and security level 2. RSA and DH keys with less than 2048 bits and ECC keys with less than 224 bits are prohibited. **PROTOCOL_TLS**, **PROTOCOL_TLS_CLIENT**, and **PROTOCOL_TLS_SERVER** use TLS 1.2 as minimum TLS version.

SSLContext objects have the following methods and attributes:

SSLContext.cert_store_stats()

Get statistics about quantities of loaded X.509 certificates, count of X.509 certificates flagged as CA certificates and certificate revocation lists as dictionary.

Example for a context with one CA cert and one other cert:

```
>>> context.cert_store_stats()
{'crl': 0, 'x509_ca': 1, 'x509': 2}
```

New in version 3.4.

SSLContext.load_cert_chain(*certfile*, *keyfile*=*None*, *password*=*None*)

Load a private key and the corresponding certificate. The *certfile* string must be the path to a single file in PEM format containing the certificate as well as any number of CA certificates needed to establish the certificate's authenticity. The *keyfile* string, if present, must point to a file containing the private key. Otherwise the private key will be taken from *certfile* as well. See the discussion of Certificates for more information on how the certificate is stored in the *certfile*.

The *password* argument may be a function to call to get the password for decrypting the private key. It will only be called if the private key is encrypted and a password is necessary. It will be called with no arguments, and it should return a string, bytes, or bytearray. If the return value is a string it will be encoded as UTF-8 before using it to decrypt the key. Alternatively a string, bytes, or bytearray value may be supplied directly as the *password* argument. It will be ignored if the private key is not encrypted and no password is needed.

If the *password* argument is not specified and a password is required, OpenSSL's built-in password prompting mechanism will be used to interactively prompt the user for a password.

An **SSLError** is raised if the private key doesn't match with the certificate.

Changed in version 3.3: New optional argument *password*.

SSLContext.load_default_certs(*purpose=Purpose.SERVER_AUTH*)

Load a set of default "certification authority" (CA) certificates from default locations. On Windows it loads CA certs from the `CA` and `ROOT` system stores. On all systems it calls **SSLContext.set_default_verify_paths()**. In the future the method may load CA certificates from other locations, too.

The *purpose* flag specifies what kind of CA certificates are loaded. The default settings **Purpose.SERVER_AUTH** loads certificates, that are flagged and trusted for TLS web server authentication (client side sockets). **Purpose.CLIENT_AUTH** loads CA certificates for client certificate verification on the server side.

New in version 3.4.

SSLContext.load_verify_locations(*cafile=None*, *capath=None*, *cadata=None*)

Load a set of "certification authority" (CA) certificates used to validate other peers' certificates when **verify_mode** is other than **CERT_NONE**. At least one of *cafile* or *capath* must be specified.

This method can also load certification revocation lists (CRLs) in PEM or DER format. In order to make use of CRLs, **SSLContext.verify_flags** must be configured properly.

The *cafile* string, if present, is the path to a file of concatenated CA certificates in PEM format. See the discussion of Certificates for more information about how to

arrange the certificates in this file.

The *capath* string, if present, is the path to a directory containing several CA certificates in PEM format, following an OpenSSL specific layout [https://www.openssl.org/docs/manmaster/man3/SSL_CTX_load_verify_locations.html].

The *cadata* object, if present, is either an ASCII string of one or more PEM-encoded certificates or a bytes-like object of DER-encoded certificates. Like with *capath* extra lines around PEM-encoded certificates are ignored but at least one certificate must be present.

Changed in version 3.4: New optional argument *cadata*

SSLContext.get_ca_certs(*binary_form=False*)

Get a list of loaded "certification authority" (CA) certificates. If the `binary_form` parameter is **`False`** each list entry is a dict like the output of **`SSLSocket.getpeercert()`**. Otherwise the method returns a list of DER-encoded certificates. The returned list does not contain certificates from *capath* unless a certificate was requested and loaded by a SSL connection.

Note

Certificates in a capath directory aren't loaded unless they have been used at least once.

New in version 3.4.

SSLContext.get_ciphers()

Get a list of enabled ciphers. The list is in order of cipher priority. See **`SSLContext.set_ciphers()`**.

Example:

```
>>> ctx = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
>>> ctx.set_ciphers('ECDHE+AESGCM:!ECDSA')
```

```
>>> ctx.get_ciphers()
[{'aead': True,
  'alg_bits': 256,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLSv1
                 'Enc=AESGCM(256) Mac=AEAD',
  'digest': None,
  'id': 50380848,
  'kea': 'kx-ecdhe',
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1.2',
  'strength_bits': 256,
  'symmetric': 'aes-256-gcm'},
 {'aead': True,
  'alg_bits': 128,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES128-GCM-SHA256 TLSv1
                 'Enc=AESGCM(128) Mac=AEAD',
  'digest': None,
  'id': 50380847,
  'kea': 'kx-ecdhe',
  'name': 'ECDHE-RSA-AES128-GCM-SHA256',
  'protocol': 'TLSv1.2',
  'strength_bits': 128,
  'symmetric': 'aes-128-gcm'}]
```

New in version 3.6.

SSLContext.set_default_verify_paths()

Load a set of default “certification authority” (CA) certificates from a filesystem path defined when building the OpenSSL library. Unfortunately, there’s no easy way to know whether this method succeeds: no error is returned if no certificates are to be found. When the OpenSSL library is provided as part of the operating system, though, it is likely to be configured properly.

SSLContext.set_ciphers(*ciphers*)

Set the available ciphers for sockets created with this context. It should be a string in the OpenSSL cipher list format [https://www.openssl.org/docs/manmaster/man1/ciphers.html]. If no cipher can be selected (because compile-time options or other configuration forbids use of all the specified ciphers), an **`SSLError`** will be raised.

Note

when connected, the **`SSLSocket.cipher()`** method of SSL sockets will give the currently selected cipher.

TLS 1.3 cipher suites cannot be disabled with **`set_ciphers()`**.

SSLContext.set_alpn_protocols(*protocols*)

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of ASCII strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to **RFC 7301** [https://datatracker.ietf.org/doc/html/rfc7301.html]. After a successful handshake, the **`SSLSocket.selected_alpn_protocol()`** method will return the agreed-upon protocol.

This method will raise **`NotImplementedError`** if **`HAS_ALPN`** is `False`.

New in version 3.5.

SSLContext.set_npn_protocols(*protocols*)

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to the Application Layer Protocol Negotiation [https://en.wikipedia.org/wiki/Application-

Layer_Protocol_Negotiation]. After a successful handshake, the **`SSLSocket.selected_npn_protocol()`** method will return the agreed-upon protocol.

This method will raise **`NotImplementedError`** if **`HAS_NPN`** is `False`.

New in version 3.3.

Deprecated since version 3.10: NPN has been superseded by ALPN

SSLContext.sni_callback

Register a callback function that will be called after the TLS Client Hello handshake message has been received by the SSL/TLS server when the TLS client specifies a server name indication. The server name indication mechanism is specified in **RFC 6066** [https://datatracker.ietf.org/doc/html/rfc6066.html] section 3 - Server Name Indication.

Only one callback can be set per `SSLContext`. If *sni_callback* is set to `None` then the callback is disabled. Calling this function a subsequent time will disable the previously registered callback.

The callback function will be called with three arguments; the first being the **`ssl.SSLSocket`**, the second is a string that represents the server name that the client is intending to communicate (or **`None`** if the TLS Client Hello does not contain a server name) and the third argument is the original **`SSLContext`**. The server name argument is text. For internationalized domain name, the server name is an IDN A-label (`"xn--pythn-mua.org"`).

A typical use of this callback is to change the **`ssl.SSLSocket`**'s **`SSLSocket.context`** attribute to a new object of type **`SSLContext`** representing a certificate chain that matches the server name.

Due to the early negotiation phase of the TLS connection, only limited methods and attributes are usable like

SSLSocket.selected_alpn_protocol() and **SSLSocket.context**. The **SSLSocket.getpeercert()**, **SSLSocket.cipher()** and **SSLSocket.compression()** methods require that the TLS connection has progressed beyond the TLS Client Hello and therefore will not return meaningful values nor can they be called safely.

The *sni_callback* function must return `None` to allow the TLS negotiation to continue. If a TLS failure is required, a constant **ALERT_DESCRIPTION_*** can be returned. Other return values will result in a TLS fatal error with **ALERT_DESCRIPTION_INTERNAL_ERROR**.

If an exception is raised from the *sni_callback* function the TLS connection will terminate with a fatal TLS alert message **ALERT_DESCRIPTION_HANDSHAKE_FAILURE**.

This method will raise **NotImplementedError** if the OpenSSL library had OPENSSL_NO_TLSEXT defined when it was built.

New in version 3.7.

SSLContext.set_servername_callback(*server_name_callback*)

This is a legacy API retained for backwards compatibility. When possible, you should use **sni_callback** instead. The given *server_name_callback* is similar to *sni_callback*, except that when the server hostname is an IDN-encoded internationalized domain name, the *server_name_callback* receives a decoded U-label (`"pythön.org"`).

If there is an decoding error on the server name, the TLS connection will terminate with an **ALERT_DESCRIPTION_INTERNAL_ERROR** fatal TLS alert message to the client.

New in version 3.4.

SSLContext.load_dh_params(*dhfile*)

Load the key generation parameters for Diffie-Hellman (DH)

key exchange. Using DH key exchange improves forward secrecy at the expense of computational resources (both on the server and on the client). The *dhfile* parameter should be the path to a file containing DH parameters in PEM format.

This setting doesn't apply to client sockets. You can also use the **OP_SINGLE_DH_USE** option to further improve security.

New in version 3.3.

SSLContext.set_ecdh_curve(*curve_name*)

Set the curve name for Elliptic Curve-based Diffie-Hellman (ECDH) key exchange. ECDH is significantly faster than regular DH while arguably as secure. The *curve_name* parameter should be a string describing a well-known elliptic curve, for example `prime256v1` for a widely supported curve.

This setting doesn't apply to client sockets. You can also use the **OP_SINGLE_ECDH_USE** option to further improve security.

This method is not available if **HAS_ECDH** is `False`.

New in version 3.3.

See also

SSL/TLS & Perfect Forward Secrecy **[https://vincent.bernat.im/en/blog/2011-ssl-perfect-forward-secrecy]**
Vincent Bernat.

SSLContext.wrap_socket(*sock*, *server_side=False*, *do_handshake_on_connect=True*, *suppress_ragged_eofs=True*, *server_hostname=None*, *session=None*)

Wrap an existing Python socket *sock* and return an instance of **SSLContext.sslsocket_class** (default **SSLSocket**). The returned SSL socket is tied to the context, its settings and

certificates. *sock* must be a **SOCK_STREAM** socket; other socket types are unsupported.

The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

For client-side sockets, the context construction is lazy; if the underlying socket isn't connected yet, the context construction will be performed after **connect()** is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the **accept()** method. The method may raise **SSLError**.

On client connections, the optional parameter *server_hostname* specifies the hostname of the service which we are connecting to. This allows a single server to host multiple SSL-based services with distinct certificates, quite similarly to HTTP virtual hosts. Specifying *server_hostname* will raise a **ValueError** if *server_side* is true.

The parameter `do_handshake_on_connect` specifies whether to do the SSL handshake automatically after doing a **socket.connect()**, or whether the application program will call it explicitly, by invoking the **SSLSocket.do_handshake()** method. Calling **SSLSocket.do_handshake()** explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter `suppress_ragged_eofs` specifies how the **SSLSocket.recv()** method should signal unexpected EOF from the other end of the connection. If specified as **True** (the default), it returns a normal EOF (an empty bytes object) in response to unexpected EOF errors raised from the underlying socket; if **False**, it will raise the exceptions back to the caller.

session, see **session**.

Changed in version 3.5: Always allow a server_hostname to be passed, even if OpenSSL does not have SNI.

Changed in version 3.6: session argument was added.

Changed in version 3.7: The method returns an instance of **SSLContext.sslsocket_class** instead of hard-coded **SSLSocket**.

SSLContext.sslsocket_class

The return type of **SSLContext.wrap_socket()**, defaults to **SSLSocket**. The attribute can be overridden on instance of class in order to return a custom subclass of **SSLSocket**.

New in version 3.7.

SSLContext.wrap_bio(*incoming*, *outgoing*, *server_side*=*False*, *server_hostname*=*None*, *session*=*None*)

Wrap the BIO objects *incoming* and *outgoing* and return an instance of **SSLContext.sslobject_class** (default **SSLObject**). The SSL routines will read input data from the incoming BIO and write data to the outgoing BIO.

The *server_side*, *server_hostname* and *session* parameters have the same meaning as in **SSLContext.wrap_socket()**.

Changed in version 3.6: session argument was added.

Changed in version 3.7: The method returns an instance of **SSLContext.sslobject_class** instead of hard-coded **SSLObject**.

SSLContext.sslobject_class

The return type of **SSLContext.wrap_bio()**, defaults to **SSLObject**. The attribute can be overridden on instance of class in order to return a custom subclass of **SSLObject**.

New in version 3.7.

SSLContext.session_stats()

Get statistics about the SSL sessions created or managed by this context. A dictionary is returned which maps the names of each piece of information [https://www.openssl.org/docs/man1.1.1/man3/SSL_CTX_sess_number.html] to their numeric values. For example, here is the total number of hits and misses in the session cache since the context was created:

```
>>> stats = context.session_stats()
>>> stats['hits'], stats['misses']
(0, 0)
```

SSLContext.check_hostname

Whether to match the peer cert's hostname in **SSLSocket.do_handshake()**. The context's **verify_mode** must be set to **CERT_OPTIONAL** or **CERT_REQUIRED**, and you must pass *server_hostname* to **wrap_socket()** in order to match the hostname. Enabling hostname checking automatically sets **verify_mode** from **CERT_NONE** to **CERT_REQUIRED**. It cannot be set back to **CERT_NONE** as long as hostname checking is enabled. The **PROTOCOL_TLS_CLIENT** protocol enables hostname checking by default. With other protocols, hostname checking must be enabled explicitly.

Example:

```
import socket, ssl

context = ssl.SSLContext(ssl.PROTOCOL_TLSv1_2)
context.verify_mode = ssl.CERT_REQUIRED
context.check_hostname = True
context.load_default_certs()

s = socket.socket(socket.AF_INET, socket.SOCK_STREA
ssl_sock = context.wrap_socket(s, server_hostname='
ssl_sock.connect(('www.verisign.com', 443))
```

New in version 3.4.

Changed in version 3.7: **verify_mode** is now automatically changed to **CERT_REQUIRED** when hostname checking is enabled and **verify_mode** is **CERT_NONE**. Previously the same operation would have failed with a **ValueError**.

SSLContext.keylog_filename

Write TLS keys to a keylog file, whenever key material is generated or received. The keylog file is designed for debugging purposes only. The file format is specified by NSS and used by many traffic analyzers such as Wireshark. The log file is opened in append-only mode. Writes are synchronized between threads, but not between processes.

New in version 3.8.

SSLContext.maximum_version

A **TLSVersion** enum member representing the highest supported TLS version. The value defaults to **TLSVersion.MAXIMUM_SUPPORTED**. The attribute is read-only for protocols other than **PROTOCOL_TLS**, **PROTOCOL_TLS_CLIENT**, and **PROTOCOL_TLS_SERVER**.

The attributes **maximum_version**, **minimum_version** and **SSLContext.options** all affect the supported SSL and TLS versions of the context. The implementation does not prevent invalid combination. For example a context with **OP_NO_TLSv1_2** in **options** and **maximum_version** set to **TLSVersion.TLSv1_2** will not be able to establish a TLS 1.2 connection.

New in version 3.7.

SSLContext.minimum_version

Like **SSLContext.maximum_version** except it is the lowest supported version or **TLSVersion.MINIMUM_SUPPORTED**.

New in version 3.7.

SSLContext.num_tickets

Control the number of TLS 1.3 session tickets of a **PROTOCOL_TLS_SERVER** context. The setting has no impact on TLS 1.0 to 1.2 connections.

New in version 3.8.

SSLContext.options

An integer representing the set of SSL options enabled on this context. The default value is **OP_ALL**, but you can specify other options such as **OP_NO_SSLv2** by ORing them together.

Changed in version 3.6: **SSLContext.options** returns **Options** flags:

```
>>> ssl.create_default_context().options
<Options.OP_ALL|OP_NO_SSLv3|OP_NO_SSLv2|OP_NO_COMPR
```

Deprecated since version 3.7: All `OP_NO_SSL*` and `OP_NO_TLS*` options have been deprecated since Python 3.7. Use **SSLContext.minimum_version** and **SSLContext.maximum_version** instead.

SSLContext.post_handshake_auth

Enable TLS 1.3 post-handshake client authentication. Post-handshake auth is disabled by default and a server can only request a TLS client certificate during the initial handshake. When enabled, a server may request a TLS client certificate at any time after the handshake.

When enabled on client-side sockets, the client signals the server that it supports post-handshake authentication.

When enabled on server-side sockets, **SSLContext.verify_mode** must be set to **CERT_OPTIONAL** or **CERT_REQUIRED**, too. The actual client cert exchange is delayed until **SSLSocket.verify_client_post_handshake()** is called and some I/O is performed.

New in version 3.8.

SSLContext.protocol

The protocol version chosen when constructing the context. This attribute is read-only.

SSLContext.hostname_checks_common_name

Whether **check_hostname** falls back to verify the cert's subject common name in the absence of a subject alternative name extension (default: true).

New in version 3.7.

Changed in version 3.10: The flag had no effect with OpenSSL before version 1.1.1k. Python 3.8.9, 3.9.3, and 3.10 include workarounds for previous versions.

SSLContext.security_level

An integer representing the security level [https://www.openssl.org/docs/manmaster/man3/SSL_CTX_get_security_level.html] for the context. This attribute is read-only.

New in version 3.10.

SSLContext.verify_flags

The flags for certificate verification operations. You can set flags like **VERIFY_CRL_CHECK_LEAF** by ORing them together. By default OpenSSL does neither require nor verify certificate revocation lists (CRLs).

New in version 3.4.

Changed in version 3.6: **SSLContext.verify_flags** returns **VerifyFlags** flags:

```
>>> ssl.create_default_context().verify_flags
<VerifyFlags.VERIFY_X509_TRUSTED_FIRST: 32768>
```

SSLContext.verify_mode

Whether to try to verify other peers' certificates and how to behave if verification fails. This attribute must be one of **CERT_NONE**, **CERT_OPTIONAL** or **CERT_REQUIRED**.

Changed in version 3.6: **SSLContext.verify_mode** returns **VerifyMode** enum:

```
>>> ssl.create_default_context().verify_mode
<VerifyMode.CERT_REQUIRED: 2>
```

Certificates

Certificates in general are part of a public-key / private-key system. In this system, each *principal*, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the *public key*; the other part is kept secret, and is called the *private key*. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and **only** with the other part.

A certificate contains information about two principals. It contains the name of a *subject*, and the subject's public key. It also contains a statement by a second principal, the *issuer*, that the subject is who they claim to be, and that this is indeed the subject's public key. The issuer's statement is signed with the issuer's private key, which only the issuer knows. However, anyone can verify the issuer's statement by finding the issuer's public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called "notBefore" and "notAfter".

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the

application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as "PEM" (see **RFC 1422** [https://datatracker.ietf.org/doc/html/rfc1422.html]), which is a base-64 encoded form wrapped with a header line and a footer line:

```
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Certificate chains

The Python files which contain certificates can contain a sequence of certificates, sometimes called a *certificate chain*. This chain should start with the specific certificate for the principal who "is" the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of *that* certificate, and so on up the chain till you get to a certificate which is *self-signed*, that is, a certificate which has the same subject and issuer, sometimes called a *root certificate*. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority's certificate:

```
-----BEGIN CERTIFICATE-----
... (certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the certificate for the CA)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

CA certificates

If you are going to require validation of the other side of the connection's certificate, you need to provide a "CA certs" file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches. The platform's certificates file can be used by calling **`SSLContext.load_default_certs()`**, this is done automatically with **`create_default_context()`**.

Combined key and certificate

Often the private key is stored in the same file as the certificate; in this case, only the `certfile` parameter to **`SSLContext.load_cert_chain()`** and **`wrap_socket()`** needs to be passed. If the private key is stored with the certificate, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
... (private key in base64 encoding) ...
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Self-signed certificates

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do this is with the OpenSSL package, using something like the following:

```
% openssl req -new -x509 -days 365 -nodes -out cert.pem
Generating a 1024 bit RSA private key
.......++++++
..............................++++++
writing new private key to 'cert.pem'
-----
```

```
You are about to be asked to enter information that will
into your certificate request.
What you are about to enter is what is called a Distingu
There are quite a few fields but you can leave some blan
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty Lt
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorgani
Email Address []:ops@myserver.mygroup.myorganization.com
%
```

The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.

Examples

Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```
try:
    import ssl
except ImportError:
    pass
else:
    ...  # do something that requires SSL support
```

Client-side operation

This example creates a SSL context with the recommended security settings for client sockets, including automatic certificate verification:

```
>>> context = ssl.create_default_context()
```

If you prefer to tune security settings yourself, you might create a context from scratch (but beware that you might not get the settings right):

```
>>> context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
>>> context.load_verify_locations("/etc/ssl/certs/ca-bur
```

(this snippet assumes your operating system places a bundle of all CA certificates in `/etc/ssl/certs/ca-bundle.crt`; if not, you'll get an error and have to adjust the location)

The **`PROTOCOL_TLS_CLIENT`** protocol configures the context for cert validation and hostname verification. **`verify_mode`** is set to **`CERT_REQUIRED`** and **`check_hostname`** is set to `True`. All other protocols create SSL contexts with insecure defaults.

When you use the context to connect to a server, **`CERT_REQUIRED`** and **`check_hostname`** validate the server certificate: it ensures that the server certificate was signed with one of the CA certificates, checks the signature for correctness, and verifies other properties like validity and identity of the hostname:

```
>>> conn = context.wrap_socket(socket.socket(socket.AF_I
...                            server_hostname="www.pyth
>>> conn.connect(("www.python.org", 443))
```

You may then fetch the certificate:

```
>>> cert = conn.getpeercert()
```

Visual inspection shows that the certificate does identify the desired service (that is, the HTTPS host `www.python.org`):

```
>>> pprint.pprint(cert)
{'OCSP': ('http://ocsp.digicert.com',),
 'caIssuers': ('http://cacerts.digicert.com/DigiCertSHA2
 'crlDistributionPoints': ('http://crl3.digicert.com/sha
                           'http://crl4.digicert.com/sha
 'issuer': ((('countryName', 'US'),),
```

```
            (('organizationName', 'DigiCert Inc'),),
            (('organizationalUnitName', 'www.digicert.co
            (('commonName', 'DigiCert SHA2 Extended Vali
 'notAfter': 'Sep  9 12:00:00 2016 GMT',
 'notBefore': 'Sep  5 00:00:00 2014 GMT',
 'serialNumber': '01BB6F00122B177F36CAB49CEA8B6B26',
 'subject': ((('businessCategory', 'Private Organizatior
             (('1.3.6.1.4.1.311.60.2.1.3', 'US'),),
             (('1.3.6.1.4.1.311.60.2.1.2', 'Delaware'),),
             (('serialNumber', '3359300'),),
             (('streetAddress', '16 Allen Rd'),),
             (('postalCode', '03894-4801'),),
             (('countryName', 'US'),),
             (('stateOrProvinceName', 'NH'),),
             (('localityName', 'Wolfeboro'),),
             (('organizationName', 'Python Software Four
             (('commonName', 'www.python.org'),)),
 'subjectAltName': (('DNS', 'www.python.org'),
                    ('DNS', 'python.org'),
                    ('DNS', 'pypi.org'),
                    ('DNS', 'docs.python.org'),
                    ('DNS', 'testpypi.org'),
                    ('DNS', 'bugs.python.org'),
                    ('DNS', 'wiki.python.org'),
                    ('DNS', 'hg.python.org'),
                    ('DNS', 'mail.python.org'),
                    ('DNS', 'packaging.python.org'),
                    ('DNS', 'pythonhosted.org'),
                    ('DNS', 'www.pythonhosted.org'),
                    ('DNS', 'test.pythonhosted.org'),
                    ('DNS', 'us.pycon.org'),
                    ('DNS', 'id.python.org')),
 'version': 3}
```

Now the SSL channel is established and the certificate verified, you can proceed to talk with the server:

```
>>> conn.sendall(b"HEAD / HTTP/1.0\r\nHost: linuxfr.org\
>>> pprint.pprint(conn.recv(1024).split(b"\r\n"))
```

```
[b'HTTP/1.1 200 OK',
 b'Date: Sat, 18 Oct 2014 18:27:20 GMT',
 b'Server: nginx',
 b'Content-Type: text/html; charset=utf-8',
 b'X-Frame-Options: SAMEORIGIN',
 b'Content-Length: 45679',
 b'Accept-Ranges: bytes',
 b'Via: 1.1 varnish',
 b'Age: 2188',
 b'X-Served-By: cache-lcy1134-LCY',
 b'X-Cache: HIT',
 b'X-Cache-Hits: 11',
 b'Vary: Cookie',
 b'Strict-Transport-Security: max-age=63072000; includeS
 b'Connection: close',
 b'',
 b'']
```

See the discussion of Security considerations below.

Server-side operation

For server operation, typically you'll need to have a server certificate, and private key, each in a file. You'll first create a context holding the key and the certificate, so that clients can check your authenticity. Then you'll open a socket, bind it to a port, call **`listen()`** on it, and start waiting for clients to connect:

```
import socket, ssl

context = ssl.create_default_context(ssl.Purpose.CLIENT_
context.load_cert_chain(certfile="mycertfile", keyfile="

bindsocket = socket.socket()
bindsocket.bind(('myaddr.example.com', 10023))
bindsocket.listen(5)
```

When a client connects, you'll call **`accept()`** on the socket to get the new socket from the other end, and use the context's

SSLContext.wrap_socket() method to create a server-side SSL socket for the connection:

```
while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = context.wrap_socket(newsocket, server_s
    try:
        deal_with_client(connstream)
    finally:
        connstream.shutdown(socket.SHUT_RDWR)
        connstream.close()
```

Then you'll read data from the `connstream` and do something with it till you are finished with the client (or the client is finished with you):

```
def deal_with_client(connstream):
    data = connstream.recv(1024)
    # empty data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.recv(1024)
    # finished with client
```

And go back to listening for new client connections (of course, a real server would probably handle each client connection in a separate thread, or put the sockets in non-blocking mode and use an event loop).

Notes on non-blocking sockets

SSL sockets behave slightly different than regular sockets in non-blocking mode. When working with non-blocking sockets, there are thus several things you need to be aware of:

- Most **SSLSocket** methods will raise either

SSLWantWriteError or **SSLWantReadError** instead of **BlockingIOError** if an I/O operation would block. **SSLWantReadError** will be raised if a read operation on the underlying socket is necessary, and **SSLWantWriteError** for a write operation on the underlying socket. Note that attempts to *write* to an SSL socket may require *reading* from the underlying socket first, and attempts to *read* from the SSL socket may require a prior *write* to the underlying socket.

Changed in version 3.5: In earlier Python versions, the **SSLSocket.send()** method returned zero instead of raising **SSLWantWriteError** or **SSLWantReadError**.

- Calling **select()** tells you that the OS-level socket can be read from (or written to), but it does not imply that there is sufficient data at the upper SSL layer. For example, only part of an SSL frame might have arrived. Therefore, you must be ready to handle **SSLSocket.recv()** and **SSLSocket.send()** failures, and retry after another call to **select()**.

- Conversely, since the SSL layer has its own framing, a SSL socket may still have data available for reading without **select()** being aware of it. Therefore, you should first call **SSLSocket.recv()** to drain any potentially available data, and then only block on a **select()** call if still necessary.

  (of course, similar provisions apply when using other primitives such as **poll()**, or those in the **selectors** module)

- The SSL handshake itself will be non-blocking: the **SSLSocket.do_handshake()** method has to be retried until it returns successfully. Here is a synopsis using **select()** to wait for the socket's readiness:

```
while True:
    try:
        sock.do_handshake()
        break
    except ssl.SSLWantReadError:
```

```
            select.select([sock], [], [])
        except ssl.SSLWantWriteError:
            select.select([], [sock], [])
```

See also

The **asyncio** module supports non-blocking SSL sockets and provides a higher level API. It polls for events using the **selectors** module and handles **SSLWantWriteError**, **SSLWantReadError** and **BlockingIOError** exceptions. It runs the SSL handshake asynchronously as well.

Memory BIO Support

New in version 3.5.

Ever since the SSL module was introduced in Python 2.6, the **SSLSocket** class has provided two related but distinct areas of functionality:

- SSL protocol handling
- Network IO

The network IO API is identical to that provided by **socket.socket**, from which **SSLSocket** also inherits. This allows an SSL socket to be used as a drop-in replacement for a regular socket, making it very easy to add SSL support to an existing application.

Combining SSL protocol handling and network IO usually works well, but there are some cases where it doesn't. An example is async IO frameworks that want to use a different IO multiplexing model than the "select/poll on a file descriptor" (readiness based) model that is assumed by **socket.socket** and by the internal OpenSSL socket IO routines. This is mostly relevant for platforms like Windows where this model is not efficient. For this purpose, a reduced scope variant of **SSLSocket** called **SSLObject** is provided.

class ssl.SSLObject

A reduced-scope variant of **`SSLSocket`** representing an SSL protocol instance that does not contain any network IO methods. This class is typically used by framework authors that want to implement asynchronous IO for SSL through memory buffers.

This class implements an interface on top of a low-level SSL object as implemented by OpenSSL. This object captures the state of an SSL connection but does not provide any network IO itself. IO needs to be performed through separate "BIO" objects which are OpenSSL's IO abstraction layer.

This class has no public constructor. An **`SSLObject`** instance must be created using the **`wrap_bio()`** method. This method will create the **`SSLObject`** instance and bind it to a pair of BIOs. The *incoming* BIO is used to pass data from Python to the SSL protocol instance, while the *outgoing* BIO is used to pass data the other way around.

The following methods are available:

- **`context`**
- **`server_side`**
- **`server_hostname`**
- **`session`**
- **`session_reused`**
- **`read()`**
- **`write()`**
- **`getpeercert()`**
- **`selected_alpn_protocol()`**
- **`selected_npn_protocol()`**
- **`cipher()`**
- **`shared_ciphers()`**
- **`compression()`**
- **`pending()`**
- **`do_handshake()`**
- **`verify_client_post_handshake()`**
- **`unwrap()`**
- **`get_channel_binding()`**

- **`version()`**

When compared to **`SSLSocket`**, this object lacks the following features:

- Any form of network IO; `recv()` and `send()` read and write only to the underlying **`MemoryBIO`** buffers.
- There is no *do_handshake_on_connect* machinery. You must always manually call **`do_handshake()`** to start the handshake.
- There is no handling of *suppress_ragged_eofs*. All end-of-file conditions that are in violation of the protocol are reported via the **`SSLEOFError`** exception.
- The method **`unwrap()`** call does not return anything, unlike for an SSL socket where it returns the underlying socket.
- The *server_name_callback* callback passed to **`SSLContext.set_servername_callback()`** will get an **`SSLObject`** instance instead of a **`SSLSocket`** instance as its first parameter.

Some notes related to the use of **`SSLObject`**:

- All IO on an **`SSLObject`** is non-blocking. This means that for example **`read()`** will raise an **`SSLWantReadError`** if it needs more data than the incoming BIO has available.
- There is no module-level `wrap_bio()` call like there is for **`wrap_socket()`**. An **`SSLObject`** is always created via an **`SSLContext`**.

Changed in version 3.7: **`SSLObject`** instances must to created with **`wrap_bio()`**. In earlier versions, it was possible to create instances directly. This was never documented or officially supported.

An SSLObject communicates with the outside world using memory buffers. The class **`MemoryBIO`** provides a memory buffer that can be used for this purpose. It wraps an OpenSSL memory BIO (Basic IO) object:

class ssl.MemoryBIO

A memory buffer that can be used to pass data between Python and an SSL protocol instance.

pending

Return the number of bytes currently in the memory buffer.

eof

A boolean indicating whether the memory BIO is current at the end-of-file position.

read(*n=-1*)

Read up to *n* bytes from the memory buffer. If *n* is not specified or negative, all bytes are returned.

write(*buf*)

Write the bytes from *buf* to the memory BIO. The *buf* argument must be an object supporting the buffer protocol.

The return value is the number of bytes written, which is always equal to the length of *buf*.

write_eof()

Write an EOF marker to the memory BIO. After this method has been called, it is illegal to call **`write()`**. The attribute **`eof`** will become true after all data currently in the buffer has been read.

SSL session

New in version 3.6.

class ssl.SSLSession

Session object used by **`session`**.

id

time

timeout

ticket_lifetime_hint

has_ticket

Security considerations

Best defaults

For **client use**, if you don't have any special requirements for your security policy, it is highly recommended that you use the **`create_default_context()`** function to create your SSL context. It will load the system's trusted CA certificates, enable certificate validation and hostname checking, and try to choose reasonably secure protocol and cipher settings.

For example, here is how you would use the **`smtplib.SMTP`** class to create a trusted, secure connection to a SMTP server:

```
>>> import ssl, smtplib
>>> smtp = smtplib.SMTP("mail.python.org", port=587)
>>> context = ssl.create_default_context()
>>> smtp.starttls(context=context)
(220, b'2.0.0 Ready to start TLS')
```

If a client certificate is needed for the connection, it can be added with **`SSLContext.load_cert_chain()`**.

By contrast, if you create the SSL context by calling the **`SSLContext`** constructor yourself, it will not have certificate validation nor hostname checking enabled by default. If you do so, please read the paragraphs below to achieve a good security level.

Manual settings

Verifying certificates

When calling the **SSLContext** constructor directly, **CERT_NONE** is the default. Since it does not authenticate the other peer, it can be insecure, especially in client mode where most of time you would like to ensure the authenticity of the server you're talking to. Therefore, when in client mode, it is highly recommended to use **CERT_REQUIRED**. However, it is in itself not sufficient; you also have to check that the server certificate, which can be obtained by calling **SSLSocket.getpeercert()**, matches the desired service. For many protocols and applications, the service can be identified by the hostname; in this case, the **match_hostname()** function can be used. This common check is automatically performed when **SSLContext.check_hostname** is enabled.

Changed in version 3.7: Hostname matchings is now performed by OpenSSL. Python no longer uses **match_hostname()**.

In server mode, if you want to authenticate your clients using the SSL layer (rather than using a higher-level authentication mechanism), you'll also have to specify **CERT_REQUIRED** and similarly check the client certificate.

Protocol versions

SSL versions 2 and 3 are considered insecure and are therefore dangerous to use. If you want maximum compatibility between clients and servers, it is recommended to use **PROTOCOL_TLS_CLIENT** or **PROTOCOL_TLS_SERVER** as the protocol version. SSLv2 and SSLv3 are disabled by default.

```
>>> client_context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLI
>>> client_context.minimum_version = ssl.TLSVersion.TLSv
>>> client_context.maximum_version = ssl.TLSVersion.TLSv
```

The SSL context created above will only allow TLSv1.2 and later (if supported by your system) connections to a server. **PROTOCOL_TLS_CLIENT** implies certificate validation and hostname checks by default. You have to load certificates into the context.

Cipher selection

If you have advanced security requirements, fine-tuning of the ciphers enabled when negotiating a SSL session is possible through the **`SSLContext.set_ciphers()`** method. Starting from Python 3.2.3, the ssl module disables certain weak ciphers by default, but you may want to further restrict the cipher choice. Be sure to read OpenSSL's documentation about the cipher list format [https://www.openssl.org/docs/man1.1.1/man1/ciphers.html#CIPHER-LIST-FORMAT]. If you want to check which ciphers are enabled by a given cipher list, use **`SSLContext.get_ciphers()`** or the `openssl ciphers` command on your system.

Multi-processing

If using this module as part of a multi-processed application (using, for example the **`multiprocessing`** or **`concurrent.futures`** modules), be aware that OpenSSL's internal random number generator does not properly handle forked processes. Applications must change the PRNG state of the parent process if they use any SSL feature with **`os.fork()`**. Any successful call of **`RAND_add()`**, **`RAND_bytes()`** or **`RAND_pseudo_bytes()`** is sufficient.

TLS 1.3

New in version 3.7.

The TLS 1.3 protocol behaves slightly differently than previous version of TLS/SSL. Some new TLS 1.3 features are not yet available.

- TLS 1.3 uses a disjunct set of cipher suites. All AES-GCM and ChaCha20 cipher suites are enabled by default. The method **`SSLContext.set_ciphers()`** cannot enable or disable any TLS 1.3 ciphers yet, but **`SSLContext.get_ciphers()`** returns them.
- Session tickets are no longer sent as part of the initial handshake and are handled differently. **`SSLSocket.session`** and **`SSLSession`** are not compatible

with TLS 1.3.

- Client-side certificates are also no longer verified during the initial handshake. A server can request a certificate at any time. Clients process certificate requests while they send or receive application data from the server.
- TLS 1.3 features like early data, deferred TLS client cert request, signature algorithm configuration, and rekeying are not supported yet.

Mozilla

`select` — Waiting for I/O completion

This module provides access to the **`select()`** and **`poll()`** functions available in most operating systems, **`devpoll()`** available on Solaris and derivatives, **`epoll()`** available on Linux 2.5+ and **`kqueue()`** available on most BSD. Note that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

Note

The **`selectors`** module allows high-level and efficient I/O multiplexing, built upon the **`select`** module primitives. Users are encouraged to use the **`selectors`** module instead, unless they want precise control over the OS-level primitives used.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The module defines the following:

exception select.error

A deprecated alias of **`OSError`**.

Changed in version 3.3: Following **PEP 3151** [https://peps.python.org/pep-3151/], this class was made an alias of **`OSError`**.

select.devpoll()

(Only supported on Solaris and derivatives.) Returns a `/dev/poll` polling object; see section /dev/poll Polling Objects below for the methods supported by devpoll objects.

`devpoll()` objects are linked to the number of file descriptors allowed at the time of instantiation. If your program reduces this value, **`devpoll()`** will fail. If your program increases this value, **`devpoll()`** may return an incomplete list of active file descriptors.

The new file descriptor is non-inheritable.

New in version 3.3.

Changed in version 3.4: The new file descriptor is now non-inheritable.

select.epoll(*sizehint=-1*, *flags=0*)

(Only supported on Linux 2.5.44 and newer.) Return an edge polling object, which can be used as Edge or Level Triggered interface for I/O events.

sizehint informs epoll about the expected number of events to be registered. It must be positive, or `-1` to use the default. It is only used on older systems where **`epoll_create1()`** is not available; otherwise it has no effect (though its value is still checked).

flags is deprecated and completely ignored. However, when supplied, its value must be `0` or `select.EPOLL_CLOEXEC`, otherwise `OSError` is raised.

See the Edge and Level Trigger Polling (epoll) Objects section below for the methods supported by epolling objects.

`epoll` objects support the context management protocol: when used in a **`with`** statement, the new file descriptor is automatically closed at the end of the block.

The new file descriptor is non-inheritable.

Changed in version 3.3: Added the *flags* parameter.

Changed in version 3.4: Support for the **with** statement was added. The new file descriptor is now non-inheritable.

Deprecated since version 3.4: The *flags* parameter. `select.EPOLL_CLOEXEC` is used by default now. Use **os.set_inheritable()** to make the file descriptor inheritable.

select.poll()

(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section Polling Objects below for the methods supported by polling objects.

select.kqueue()

(Only supported on BSD.) Returns a kernel queue object; see section Kqueue Objects below for the methods supported by kqueue objects.

The new file descriptor is non-inheritable.

Changed in version 3.4: The new file descriptor is now non-inheritable.

select.kevent(*ident*, *filter*=*KQ_FILTER_READ*, *flags*=*KQ_EV_ADD*, *fflags*=*0*, *data*=*0*, *udata*=*0*)

(Only supported on BSD.) Returns a kernel event object; see section Kevent Objects below for the methods supported by kevent objects.

select.select(*rlist*, *wlist*, *xlist*[, *timeout*])

This is a straightforward interface to the Unix **select()** system call. The first three arguments are iterables of

'waitable objects': either integers representing file descriptors or objects with a parameterless method named **`fileno()`** returning such an integer:

- *rlist*: wait until ready for reading
- *wlist*: wait until ready for writing
- *xlist*: wait for an "exceptional condition" (see the manual page for what your system considers such a condition)

Empty iterables are allowed, but acceptance of three empty iterables is platform-dependent. (It is known to work on Unix but not on Windows.) The optional *timeout* argument specifies a time-out as a floating point number in seconds. When the *timeout* argument is omitted the function blocks until at least one file descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the iterables are Python file objects (e.g. `sys.stdin`, or objects returned by **`open()`** or **`os.popen()`**), socket objects returned by **`socket.socket()`**. You may also define a *wrapper* class yourself, as long as it has an appropriate **`fileno()`** method (that really returns a file descriptor, not just a random integer).

Note

File objects on Windows are not acceptable, but sockets are. On Windows, the underlying **`select()`** function is provided by the WinSock library, and does not handle file descriptors that don't originate from WinSock.

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** [https://

peps.python.org/pep-0475/] for the rationale), instead of raising **InterruptedError**.

select.PIPE_BUF

The minimum number of bytes which can be written without blocking to a pipe when the pipe has been reported as ready for writing by **select()**, **poll()** or another interface in this module. This doesn't apply to other kind of file-like objects such as sockets.

This value is guaranteed by POSIX to be at least 512.

Availability: Unix

New in version 3.2.

/dev/poll Polling Objects

Solaris and derivatives have `/dev/poll`. While **select()** is O(highest file descriptor) and **poll()** is O(number of file descriptors), `/dev/poll` is O(active file descriptors).

`/dev/poll` behaviour is very close to the standard **poll()** object.

devpoll.close()

Close the file descriptor of the polling object.

New in version 3.4.

devpoll.closed

`True` if the polling object is closed.

New in version 3.4.

devpoll.fileno()

Return the file descriptor number of the polling object.

New in version 3.4.

devpoll.register(*fd*[, *eventmask*])

Register a file descriptor with the polling object. Future calls to the **poll()** method will then check whether the file descriptor has any pending I/O events. *fd* can be either an integer, or an object with a **fileno()** method that returns an integer. File objects implement **fileno()**, so they can also be used as the argument.

eventmask is an optional bitmask describing the type of events you want to check for. The constants are the same that with **poll()** object. The default value is a combination of the constants **POLLIN**, **POLLPRI**, and **POLLOUT**.

Warning

Registering a file descriptor that's already registered is not an error, but the result is undefined. The appropriate action is to unregister or modify it first. This is an important difference compared with **poll()**.

devpoll.modify(*fd*[, *eventmask*])

This method does an **unregister()** followed by a **register()**. It is (a bit) more efficient that doing the same explicitly.

devpoll.unregister(*fd*)

Remove a file descriptor being tracked by a polling object. Just like the **register()** method, *fd* can be an integer or an object with a **fileno()** method that returns an integer.

Attempting to remove a file descriptor that was never registered is safely ignored.

devpoll.poll([*timeout*])

Polls the set of registered file descriptors, and returns a possibly empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. *fd* is the file

descriptor, and *event* is a bitmask with bits set for the reported events for that descriptor — **POLLIN** for waiting input, **POLLOUT** to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If *timeout* is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If *timeout* is omitted, -1, or **None**, the call will block until there is an event for this poll object.

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale), instead of raising **InterruptedError**.

Edge and Level Trigger Polling (epoll) Objects

https://linux.die.net/man/4/epoll

eventmask

Constant	Meaning
EPOLLIN	Available for read
EPOLLOUT	Available for write
EPOLLPRI	Urgent data for read
EPOLLERR	Error condition happened on the assoc. fd
EPOLLHUP	Hang up happened on the assoc. fd
EPOLLET	Set Edge Trigger behavior, the default is Level Trigger behavior
EPOLLONESHOT	Set one-shot behavior. After one event is pulled out, the fd is internally disabled
EPOLLEXCLUSIVE	Wake only one epoll object when the associated fd has an event. The default (if this flag is not set) is to wake all epoll objects polling on a fd.
EPOLLRDHUP	Stream socket peer closed connection or shut down writing half of connection.
EPOLLRDNORM	Equivalent to **EPOLLIN**

EPOLLPRI	There is urgent data available for read(2) operations.
EPOLLERR	Error condition happened on the associated file descriptor. This event is also reported for the write end of a pipe when the read end has been closed. **epoll_wait(2)** will always report for this event; it is not necessary to set it in *eventmask*.
EPOLLHUP	Hang up happened on the associated file descriptor. **epoll_wait(2)** will always wait for this event; it is not necessary to set it in *eventmask*.
EPOLLRDHUP	Stream socket peer closed connection, or shut down writing half of connection. (This flag is especially useful for writing simple code to detect peer shutdown when using Edge Triggered monitoring.)
EPOLLEXCLUSIVE	Sets an exclusive wakeup mode for the epoll file descriptor that is being attached to the target file descriptor, *fd*. When a wakeup event occurs and multiple epoll file descriptors are attached to the same target file using **EPOLLEXCLUSIVE**, one or more of the epoll file descriptors will receive an event with **epoll_wait(2)**. The default in this scenario (when **EPOLLEXCLUSIVE** is not set) is for all epoll file descriptors to receive an event. **EPOLLEXCLUSIVE** is thus useful for avoiding thundering herd problems in certain scenarios.
EPOLLET	Sets the Edge Triggered behavior for the associated file descriptor. The default behavior for epoll is Level Triggered. See **epoll(7)** for more detailed information about Edge and Level Triggered event distribution architectures.
EPOLLONESHOT	Sets the one-shot behavior for the associated file descriptor. This means that after an event is pulled out with **epoll_wait(2)** the associated file descriptor is internally disabled and no other events will be reported by the epoll interface. The user must call **EPOLL_CTL_MOD** to rearm the file descriptor with a new event mask.

New in version 3.6: **EPOLLEXCLUSIVE** was added. It's only supported by Linux Kernel 4.5 or later.

epoll.close()

Close the control file descriptor of the epoll object.

epoll.closed

`True` if the epoll object is closed.

epoll.fileno()

Return the file descriptor number of the control fd.

epoll.fromfd(*fd*)

Create an epoll object from a given file descriptor.

epoll.register(*fd*[, *eventmask*])

Register a fd descriptor with the epoll object.

epoll.modify(*fd*, *eventmask*)

Modify a registered file descriptor.

epoll.unregister(*fd*)

Remove a registered file descriptor from the epoll object.

Changed in version 3.9: The method no longer ignores the **EBADF** error.

epoll.poll(*timeout=None*, *maxevents=-1*)

Wait for events. timeout in seconds (float)

Changed in version 3.5: The function is now retried with a

recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale), instead of raising **`InterruptedError`**.

Polling Objects

The **`poll()`** system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. **`poll()`** scales better because the system call only requires listing the file descriptors of interest, while **`select()`** builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. **`select()`** is O(highest file descriptor), while **`poll()`** is O(number of file descriptors).

poll.register(*fd*[, *eventmask*])

Register a file descriptor with the polling object. Future calls to the **`poll()`** method will then check whether the file descriptor has any pending I/O events. *fd* can be either an integer, or an object with a **`fileno()`** method that returns an integer. File objects implement **`fileno()`**, so they can also be used as the argument.

eventmask is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants **`POLLIN`**, **`POLLPRI`**, and **`POLLOUT`**, described in the table below. If not specified, the default value used will check for all 3 types of events.

Constant	Meaning
`POLLIN`	There is data to read
`POLLPRI`	There is urgent data to read
`POLLOUT`	Ready for output: writing will not block
`POLLERR`	Error condition of some sort
`POLLHUP`	Hung up
`POLLRDHUP`	Stream socket peer closed connection, or shut down writing half of connection
`POLLNVAL`	Invalid request: descriptor not open

Registering a file descriptor that's already registered is not an error, and has the same effect as registering the descriptor exactly once.

poll.modify(*fd*, *eventmask*)

Modifies an already registered fd. This has the same effect as `register(fd, eventmask)`. Attempting to modify a file descriptor that was never registered causes an **OSError** exception with errno **ENOENT** to be raised.

poll.unregister(*fd*)

Remove a file descriptor being tracked by a polling object. Just like the **register()** method, *fd* can be an integer or an object with a **fileno()** method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a **KeyError** exception to be raised.

poll.poll([*timeout*])

Polls the set of registered file descriptors, and returns a possibly empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. *fd* is the file descriptor, and *event* is a bitmask with bits set for the reported events for that descriptor — **POLLIN** for waiting input, **POLLOUT** to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If *timeout* is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If *timeout* is omitted, negative, or **None**, the call will block until there is an event for this poll object.

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale), instead of raising **InterruptedError**.

Kqueue Objects

kqueue.close()

Close the control file descriptor of the kqueue object.

kqueue.closed

`True` if the kqueue object is closed.

kqueue.fileno()

Return the file descriptor number of the control fd.

kqueue.fromfd(*fd*)

Create a kqueue object from a given file descriptor.

kqueue.control(*changelist*, *max_events*[, *timeout*]) → eventlist

Low level interface to kevent

- changelist must be an iterable of kevent objects or `None`
- max_events must be 0 or a positive integer
- timeout in seconds (floats possible); the default is `None`, to wait forever

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale), instead of raising **`InterruptedError`**.

Kevent Objects

https://www.freebsd.org/cgi/man.cgi?query=kqueue&sektion=2

kevent.ident

Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor ident can either be an int or an object with a

`fileno()` method. kevent stores the integer internally.

kevent.filter

Name of the kernel filter.

Constant	Meaning
`KQ_FILTER_READ`	Takes a descriptor and returns whenever there is data available to read
`KQ_FILTER_WRITE`	Takes a descriptor and returns whenever there is data available to write
`KQ_FILTER_AIO`	AIO requests
`KQ_FILTER_VNODE`	Returns when one or more of the requested events watched in *fflag* occurs
`KQ_FILTER_PROC`	Watch for events on a process id
`KQ_FILTER_NETDEV`	Watch for events on a network device [not available on macOS]
`KQ_FILTER_SIGNAL`	Returns whenever the watched signal is delivered to the process
`KQ_FILTER_TIMER`	Establishes an arbitrary timer

kevent.flags

Filter action.

Constant	Meaning
`KQ_EV_ADD`	Adds or modifies an event
`KQ_EV_DELETE`	Removes an event from the queue
`KQ_EV_ENABLE`	Permits `control()` to returns the event
`KQ_EV_DISABLE`	Disables event
`KQ_EV_ONESHOT`	Removes event after first occurrence
`KQ_EV_CLEAR`	Reset state after an event is retrieved
`KQ_EV_SYSFLAGS`	internal event
`KQ_EV_FLAG1`	internal event
`KQ_EV_EOF`	Filter specific EOF condition
`KQ_EV_ERROR`	See return values

kevent.fflags

Filter specific flags.

`KQ_FILTER_READ` and `KQ_FILTER_WRITE` filter flags:

Constant	Meaning

Value	Meaning
NOTE_LOWAT	low water mark of a socket buffer

KQ_FILTER_VNODE filter flags:

Value	Meaning
NOTE_DELETE	*unlink()* was called
NOTE_WRITE	a write occurred
NOTE_EXTEND	the file was extended
NOTE_ATTRIB	an attribute was changed
NOTE_LINK	the link count has changed
NOTE_RENAME	the file was renamed
NOTE_REVOKE	access to the file was revoked

KQ_FILTER_PROC filter flags:

Value	Meaning
NOTE_EXIT	the process has exited
NOTE_FORK	the process has called *fork()*
NOTE_EXEC	the process has executed a new process
NOTE_PCTRLMASK	internal filter flag
NOTE_PDATAMASK	internal filter flag
NOTE_TRACK	follow a process across *fork()*
NOTE_CHILD	returned on the child process for *NOTE_TRACK*
NOTE_TRACKERR	unable to attach a child

KQ_FILTER_NETDEV filter flags (not available on macOS):

Value	Meaning
NOTE_LINKUP	link is up
NOTE_LINKDOWN	link is down
NOTE_LINKINV	link state is invalid

kevent.data

Filter specific data.

kevent.udata

User defined value.

`selectors` — High-level I/O multiplexing

New in version 3.4.

Source code: Lib/selectors.py [https://github.com/python/cpython/tree/3.11/Lib/selectors.py]

Introduction

This module allows high-level and efficient I/O multiplexing, built upon the `select` module primitives. Users are encouraged to use this module instead, unless they want precise control over the OS-level primitives used.

It defines a `BaseSelector` abstract base class, along with several concrete implementations (`KqueueSelector`, `EpollSelector`…), that can be used to wait for I/O readiness notification on multiple file objects. In the following, "file object" refers to any object with a `fileno()` method, or a raw file descriptor. See file object.

`DefaultSelector` is an alias to the most efficient implementation available on the current platform: this should be the default choice for most users.

Note

The type of file objects supported depends on the platform: on Windows, sockets are supported, but not pipes, whereas on Unix, both are supported (some other types may be supported as well, such as fifos or special file devices).

See also

`select`
Low-level I/O multiplexing module.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Classes

Classes hierarchy:

```
BaseSelector
+-- SelectSelector
+-- PollSelector
+-- EpollSelector
+-- DevpollSelector
+-- KqueueSelector
```

In the following, *events* is a bitwise mask indicating which I/O events should be waited for on a given file object. It can be a combination of the modules constants below:

Constant	Meaning
EVENT_READ	available for read
EVENT_WRITE	available for write

class selectors.SelectorKey

A **`SelectorKey`** is a **`namedtuple`** used to associate a file object to its underlying file descriptor, selected event mask and attached data. It is returned by several **`BaseSelector`** methods.

fileobj
File object registered.

fd

Underlying file descriptor.

events

Events that must be waited for on this file object.

data

Optional opaque data associated to this file object: for example, this could be used to store a per-client session ID.

class selectors.BaseSelector

A **`BaseSelector`** is used to wait for I/O event readiness on multiple file objects. It supports file stream registration, unregistration, and a method to wait for I/O events on those streams, with an optional timeout. It's an abstract base class, so cannot be instantiated. Use **`DefaultSelector`** instead, or one of **`SelectSelector`**, **`KqueueSelector`** etc. if you want to specifically use an implementation, and your platform supports it. **`BaseSelector`** and its concrete implementations support the context manager protocol.

abstractmethod register(*fileobj*, *events*, *data*=*None*)

Register a file object for selection, monitoring it for I/O events.

fileobj is the file object to monitor. It may either be an integer file descriptor or an object with a `fileno()` method. *events* is a bitwise mask of events to monitor. *data* is an opaque object.

This returns a new **`SelectorKey`** instance, or raises a **`ValueError`** in case of invalid event mask or file descriptor, or **`KeyError`** if the file object is already registered.

abstractmethod unregister(*fileobj*)

Unregister a file object from selection, removing it from

monitoring. A file object shall be unregistered prior to being closed.

fileobj must be a file object previously registered.

This returns the associated **`SelectorKey`** instance, or raises a **`KeyError`** if *fileobj* is not registered. It will raise **`ValueError`** if *fileobj* is invalid (e.g. it has no `fileno()` method or its `fileno()` method has an invalid return value).

modify(*fileobj*, *events*, *data*=*None*)

Change a registered file object's monitored events or attached data.

This is equivalent to **`BaseSelector.unregister(fileobj)()`** followed by **`BaseSelector.register(fileobj, events, data)()`**, except that it can be implemented more efficiently.

This returns a new **`SelectorKey`** instance, or raises a **`ValueError`** in case of invalid event mask or file descriptor, or **`KeyError`** if the file object is not registered.

abstractmethod select(*timeout*=*None*)

Wait until some registered file objects become ready, or the timeout expires.

If `timeout > 0`, this specifies the maximum wait time, in seconds. If `timeout <= 0`, the call won't block, and will report the currently ready file objects. If *timeout* is `None`, the call will block until a monitored file object becomes ready.

This returns a list of `(key, events)` tuples, one for each ready file object.

key is the **`SelectorKey`** instance corresponding to a

ready file object. *events* is a bitmask of events ready on this file object.

Note

This method can return before any file object becomes ready or the timeout has elapsed if the current process receives a signal: in this case, an empty list will be returned.

Changed in version 3.5: The selector is now retried with a recomputed timeout when interrupted by a signal if the signal handler did not raise an exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale), instead of returning an empty list of events before the timeout.

close()

Close the selector.

This must be called to make sure that any underlying resource is freed. The selector shall not be used once it has been closed.

get_key(*fileobj*)

Return the key associated with a registered file object.

This returns the **SelectorKey** instance associated to this file object, or raises **KeyError** if the file object is not registered.

abstractmethod get_map()

Return a mapping of file objects to selector keys.

This returns a **Mapping** instance mapping registered file objects to their associated **SelectorKey** instance.

class selectors.DefaultSelector

The default selector class, using the most efficient implementation available on the current platform. This should be the default choice for most users.

class selectors.SelectSelector

select.select()-based selector.

class selectors.PollSelector

select.poll()-based selector.

class selectors.EpollSelector

select.epoll()-based selector.

fileno()

This returns the file descriptor used by the underlying **select.epoll()** object.

class selectors.DevpollSelector

select.devpoll()-based selector.

fileno()

This returns the file descriptor used by the underlying **select.devpoll()** object.

New in version 3.5.

class selectors.KqueueSelector

select.kqueue()-based selector.

fileno()

This returns the file descriptor used by the underlying **select.kqueue()** object.

Examples

Here is a simple echo server implementation:

```
import selectors
import socket

sel = selectors.DefaultSelector()

def accept(sock, mask):
    conn, addr = sock.accept()  # Should be ready
    print('accepted', conn, 'from', addr)
    conn.setblocking(False)
    sel.register(conn, selectors.EVENT_READ, read)

def read(conn, mask):
    data = conn.recv(1000)  # Should be ready
    if data:
        print('echoing', repr(data), 'to', conn)
        conn.send(data)  # Hope it won't block
    else:
        print('closing', conn)
        sel.unregister(conn)
        conn.close()

sock = socket.socket()
sock.bind(('localhost', 1234))
sock.listen(100)
sock.setblocking(False)
sel.register(sock, selectors.EVENT_READ, accept)

while True:
    events = sel.select()
    for key, mask in events:
        callback = key.data
        callback(key.fileobj, mask)
```

`signal` — Set handlers for asynchronous events

Source code: Lib/signal.py [https://github.com/python/cpython/tree/3.11/Lib/signal.py]

This module provides mechanisms to use signal handlers in Python.

General rules

The `signal.signal()` function allows defining custom handlers to be executed when a signal is received. A small number of default handlers are installed: `SIGPIPE` is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and `SIGINT` is translated into a `KeyboardInterrupt` exception if the parent process has not changed it.

A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for `SIGCHLD`, which follows the underlying implementation.

On WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`, signals are emulated and therefore behave differently. Several functions and signals are not available on these platforms.

Execution of Python signal handlers

A Python signal handler does not get executed inside the low-level (C) signal handler. Instead, the low-level signal handler sets a flag which tells the virtual machine to execute the corresponding Python signal handler at a later point(for example at the next bytecode instruction). This has consequences:

- It makes little sense to catch synchronous errors like **SIGFPE** or **SIGSEGV** that are caused by an invalid operation in C code. Python will return from the signal handler to the C code, which is likely to raise the same signal again, causing Python to apparently hang. From Python 3.3 onwards, you can use the **faulthandler** module to report on synchronous errors.
- A long-running calculation implemented purely in C (such as regular expression matching on a large body of text) may run uninterrupted for an arbitrary amount of time, regardless of any signals received. The Python signal handlers will be called when the calculation finishes.
- If the handler raises an exception, it will be raised "out of thin air" in the main thread. See the note below for a discussion.

Signals and threads

Python signal handlers are always executed in the main Python thread of the main interpreter, even if the signal was received in another thread. This means that signals can't be used as a means of inter-thread communication. You can use the synchronization primitives from the **threading** module instead.

Besides, only the main thread of the main interpreter is allowed to set a new signal handler.

Module contents

Changed in version 3.5: signal (SIG*), handler (**SIG_DFL**, **SIG_IGN**) and sigmask (**SIG_BLOCK**, **SIG_UNBLOCK**, **SIG_SETMASK**) related constants listed below were turned into **enums** (**Signals**, **Handlers** and **Sigmasks** respectively). **getsignal()**, **pthread_sigmask()**, **sigpending()** and **sigwait()** functions return human-readable **enums** as **Signals** objects.

The signal module defines three enums:

class signal.Signals

enum.IntEnum collection of SIG* constants and the CTRL_*

constants.

New in version 3.5.

class signal.Handlers

enum.IntEnum collection the constants **SIG_DFL** and **SIG_IGN**.

New in version 3.5.

class signal.Sigmasks

enum.IntEnum collection the constants **SIG_BLOCK**, **SIG_UNBLOCK** and **SIG_SETMASK**.

Availability: Unix.

See the man page *sigprocmask(2)* and *pthread_sigmask(3)* for further information.

New in version 3.5.

The variables defined in the **signal** module are:

signal.SIG_DFL

This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for **SIGQUIT** is to dump core and exit, while the default action for **SIGCHLD** is to simply ignore it.

signal.SIG_IGN

This is another standard signal handler, which will simply ignore the given signal.

signal.SIGABRT

Abort signal from *abort(3)*.

signal.SIGALRM

Timer signal from *alarm(2)*.

Availability: Unix.

signal.SIGBREAK
: Interrupt from keyboard (CTRL + BREAK).

  Availability: Windows.

signal.SIGBUS
: Bus error (bad memory access).

  Availability: Unix.

signal.SIGCHLD
: Child process stopped or terminated.

  Availability: Unix.

signal.SIGCLD
: Alias to `SIGCHLD`.

signal.SIGCONT
: Continue the process if it is currently stopped

  Availability: Unix.

signal.SIGFPE
: Floating-point exception. For example, division by zero.

  See also

  `ZeroDivisionError` is raised when the second argument of a division or modulo operation is zero.

signal.SIGHUP
: Hangup detected on controlling terminal or death of

controlling process.

Availability: Unix.

signal.SIGILL
: Illegal instruction.

signal.SIGINT
: Interrupt from keyboard (CTRL + C).

  Default action is to raise **`KeyboardInterrupt`**.

signal.SIGKILL
: Kill signal.

  It cannot be caught, blocked, or ignored.

  Availability: Unix.

signal.SIGPIPE
: Broken pipe: write to pipe with no readers.

  Default action is to ignore the signal.

  Availability: Unix.

signal.SIGSEGV
: Segmentation fault: invalid memory reference.

signal.SIGSTKFLT

> Stack fault on coprocessor. The Linux kernel does not raise this signal: it can only be raised in user space.

Availability: Linux.

On architectures where the signal is available. See the man page *signal(7)* for further information.

New in version 3.11.

signal.SIGTERM
: Termination signal.

signal.SIGUSR1
: User-defined signal 1.

  Availability: Unix.

signal.SIGUSR2
: User-defined signal 2.

  Availability: Unix.

signal.SIGWINCH
: Window resize signal.

  Availability: Unix.

SIG*
: All the signal numbers are defined symbolically. For example, the hangup signal is defined as **`signal.SIGHUP`**; the variable names are identical to the names used in C programs, as found in `<signal.h>`. The Unix man page for '**`signal()`**' lists the existing signals (on some systems this is *signal(2)*, on others the list is in *signal(7)*). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

signal.CTRL_C_EVENT
: The signal corresponding to the `Ctrl+C` keystroke event. This signal can only be used with **`os.kill()`**.

  Availability: Windows.

  New in version 3.2.

signal.CTRL_BREAK_EVENT

The signal corresponding to the `Ctrl+Break` keystroke event. This signal can only be used with **`os.kill()`**.

Availability: Windows.

New in version 3.2.

signal.NSIG

One more than the number of the highest signal number. Use **`valid_signals()`** to get valid signal numbers.

signal.ITIMER_REAL

Decrements interval timer in real time, and delivers **`SIGALRM`** upon expiration.

signal.ITIMER_VIRTUAL

Decrements interval timer only when the process is executing, and delivers SIGVTALRM upon expiration.

signal.ITIMER_PROF

Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with ITIMER_VIRTUAL, this timer is usually used to profile the time spent by the application in user and kernel space. SIGPROF is delivered upon expiration.

signal.SIG_BLOCK

A possible value for the *how* parameter to **`pthread_sigmask()`** indicating that signals are to be blocked.

New in version 3.3.

signal.SIG_UNBLOCK

A possible value for the *how* parameter to **`pthread_sigmask()`** indicating that signals are to be unblocked.

New in version 3.3.

signal.SIG_SETMASK

A possible value for the *how* parameter to **pthread_sigmask()** indicating that the signal mask is to be replaced.

New in version 3.3.

The **signal** module defines one exception:

exception signal.ItimerError

Raised to signal an error from the underlying **setitimer()** or **getitimer()** implementation. Expect this error if an invalid interval timer or a negative time is passed to **setitimer()**. This error is a subtype of **OSError**.

New in version 3.3: This error used to be a subtype of **IOError**, which is now an alias of **OSError**.

The **signal** module defines the following functions:

signal.alarm(*time*)

If *time* is non-zero, this function requests that a **SIGALRM** signal be sent to the process in *time* seconds. Any previously scheduled alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If *time* is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled.

Availability: Unix.

See the man page *alarm(2)* for further information.

signal.getsignal(*signalnum*)

Return the current signal handler for the signal *signalnum*.

The returned value may be a callable Python object, or one of the special values **signal.SIG_IGN**, **signal.SIG_DFL** or **None**. Here, **signal.SIG_IGN** means that the signal was previously ignored, **signal.SIG_DFL** means that the default way of handling the signal was previously in use, and None means that the previous signal handler was not installed from Python.

signal.strsignal(*signalnum*)

Returns the description of signal *signalnum*, such as "Interrupt" for **SIGINT**. Returns **None** if *signalnum* has no description. Raises **ValueError** if *signalnum* is invalid.

New in version 3.8.

signal.valid_signals()

Return the set of valid signal numbers on this platform. This can be less than `range(1, NSIG)` if some signals are reserved by the system for internal use.

New in version 3.8.

signal.pause()

Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing.

Availability: Unix.

See the man page *signal(2)* for further information.

See also **sigwait()**, **sigwaitinfo()**, **sigtimedwait()** and **sigpending()**.

signal.raise_signal(*signum*)

Sends a signal to the calling process. Returns nothing.

New in version 3.8.

signal.pidfd_send_signal(*pidfd*, *sig*, *siginfo=None*, *flags=0*)

Send signal *sig* to the process referred to by file descriptor *pidfd*. Python does not currently support the *siginfo* parameter; it must be `None`. The *flags* argument is provided for future extensions; no flag values are currently defined.

See the *pidfd_send_signal(2)* man page for more information.

Availability: Linux >= 5.1

New in version 3.9.

signal.pthread_kill(*thread_id*, *signalnum*)

Send the signal *signalnum* to the thread *thread_id*, another thread in the same process as the caller. The target thread can be executing any code (Python or not). However, if the target thread is executing the Python interpreter, the Python signal handlers will be executed by the main thread of the main interpreter. Therefore, the only point of sending a signal to a particular Python thread would be to force a running system call to fail with **`InterruptedError`**.

Use **`threading.get_ident()`** or the **`ident`** attribute of **`threading.Thread`** objects to get a suitable value for *thread_id*.

If *signalnum* is 0, then no signal is sent, but error checking is still performed; this can be used to check if the target thread is still running.

Raises an auditing event `signal.pthread_kill` with arguments `thread_id`, `signalnum`.

Availability: Unix.

See the man page *pthread_kill(3)* for further information.

See also **`os.kill()`**.

New in version 3.3.

signal.pthread_sigmask(*how*, *mask*)

Fetch and/or change the signal mask of the calling thread. The signal mask is the set of signals whose delivery is currently blocked for the caller. Return the old signal mask as a set of signals.

The behavior of the call is dependent on the value of *how*, as follows.

- **SIG_BLOCK**: The set of blocked signals is the union of the current set and the *mask* argument.
- **SIG_UNBLOCK**: The signals in *mask* are removed from the current set of blocked signals. It is permissible to attempt to unblock a signal which is not blocked.
- **SIG_SETMASK**: The set of blocked signals is set to the *mask* argument.

mask is a set of signal numbers (e.g. {**signal.SIGINT**, **signal.SIGTERM**}). Use **valid_signals()** for a full mask including all signals.

For example, `signal.pthread_sigmask(signal.SIG_BLOCK, [])` reads the signal mask of the calling thread.

SIGKILL and **SIGSTOP** cannot be blocked.

Availability: Unix.

See the man page *sigprocmask(2)* and *pthread_sigmask(3)* for further information.

See also **pause()**, **sigpending()** and **sigwait()**.

New in version 3.3.

signal.setitimer(*which*, *seconds*, *interval=0.0*)

Sets given interval timer (one of **signal.ITIMER_REAL**, **signal.ITIMER_VIRTUAL** or **signal.ITIMER_PROF**) specified by *which* to fire after *seconds* (float is accepted,

different from **alarm()**) and after that every *interval* seconds (if *interval* is non-zero). The interval timer specified by *which* can be cleared by setting *seconds* to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; **signal.ITIMER_REAL** will deliver **SIGALRM**, **signal.ITIMER_VIRTUAL** sends **SIGVTALRM**, and **signal.ITIMER_PROF** will deliver **SIGPROF**.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause an **ItimerError**.

Availability: Unix.

signal.getitimer(*which*)

Returns current value of a given interval timer specified by *which*.

Availability: Unix.

signal.set_wakeup_fd(*fd*, *, *warn_on_full_buffer=True*)

Set the wakeup file descriptor to *fd*. When a signal is received, the signal number is written as a single byte into the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned (or -1 if file descriptor wakeup was not enabled). If *fd* is -1, file descriptor wakeup is disabled. If not -1, *fd* must be non-blocking. It is up to the library to remove any bytes from *fd* before calling poll or select again.

When threads are enabled, this function can only be called from the main thread of the main interpreter; attempting to call it from other threads will cause a **ValueError** exception to be raised.

There are two common ways to use this function. In both approaches, you use the fd to wake up when a signal arrives, but then they differ in how they determine *which* signal or signals have arrived.

In the first approach, we read the data out of the fd's buffer, and the byte values give you the signal numbers. This is simple, but in rare cases it can run into a problem: generally the fd will have a limited amount of buffer space, and if too many signals arrive too quickly, then the buffer may become full, and some signals may be lost. If you use this approach, then you should set `warn_on_full_buffer=True`, which will at least cause a warning to be printed to stderr when signals are lost.

In the second approach, we use the wakeup fd *only* for wakeups, and ignore the actual byte values. In this case, all we care about is whether the fd's buffer is empty or non-empty; a full buffer doesn't indicate a problem at all. If you use this approach, then you should set `warn_on_full_buffer=False`, so that your users are not confused by spurious warning messages.

Changed in version 3.5: On Windows, the function now also supports socket handles.

Changed in version 3.7: Added `warn_on_full_buffer` parameter.

signal.siginterrupt(*signalnum*, *flag*)

Change system call restart behaviour: if *flag* is **`False`**, system calls will be restarted when interrupted by signal *signalnum*, otherwise system calls will be interrupted. Returns nothing.

Availability: Unix.

See the man page *siginterrupt(3)* for further information.

Note that installing a signal handler with **`signal()`** will reset the restart behaviour to interruptible by implicitly

calling **`siginterrupt()`** with a true *flag* value for the given signal.

signal.signal(*signalnum*, *handler*)

Set the handler for signal *signalnum* to the function *handler*. *handler* can be a callable Python object taking two arguments (see below), or one of the special values **`signal.SIG_IGN`** or **`signal.SIG_DFL`**. The previous signal handler will be returned (see the description of **`getsignal()`** above). (See the Unix man page *signal(2)* for further information.)

When threads are enabled, this function can only be called from the main thread of the main interpreter; attempting to call it from other threads will cause a **`ValueError`** exception to be raised.

The *handler* is called with two arguments: the signal number and the current stack frame (`None` or a frame object; for a description of frame objects, see the description in the type hierarchy or see the attribute descriptions in the **`inspect`** module).

On Windows, **`signal()`** can only be called with **`SIGABRT`**, **`SIGFPE`**, **`SIGILL`**, **`SIGINT`**, **`SIGSEGV`**, **`SIGTERM`**, or **`SIGBREAK`**. A **`ValueError`** will be raised in any other case. Note that not all systems define the same set of signal names; an **`AttributeError`** will be raised if a signal name is not defined as `SIG*` module level constant.

signal.sigpending()

Examine the set of signals that are pending for delivery to the calling thread (i.e., the signals which have been raised while blocked). Return the set of the pending signals.

Availability: Unix.

See the man page *sigpending(2)* for further information.

See also **`pause()`**, **`pthread_sigmask()`** and **`sigwait()`**.

New in version 3.3.

signal.sigwait(*sigset*)

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set *sigset*. The function accepts the signal (removes it from the pending list of signals), and returns the signal number.

Availability: Unix.

See the man page *sigwait(3)* for further information.

See also **`pause()`**, **`pthread_sigmask()`**, **`sigpending()`**, **`sigwaitinfo()`** and **`sigtimedwait()`**.

New in version 3.3.

signal.sigwaitinfo(*sigset*)

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set *sigset*. The function accepts the signal and removes it from the pending list of signals. If one of the signals in *sigset* is already pending for the calling thread, the function will return immediately with information about that signal. The signal handler is not called for the delivered signal. The function raises an **`InterruptedError`** if it is interrupted by a signal that is not in *sigset*.

The return value is an object representing the data contained in the **`siginfo_t`** structure, namely: **`si_signo`**, **`si_code`**, **`si_errno`**, **`si_pid`**, **`si_uid`**, **`si_status`**, **`si_band`**.

Availability: Unix.

See the man page *sigwaitinfo(2)* for further information.

See also **`pause()`**, **`sigwait()`** and **`sigtimedwait()`**.

New in version 3.3.

Changed in version 3.5: The function is now retried if interrupted by a signal not in *sigset* and the signal handler does not raise an exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

signal.sigtimedwait(*sigset*, *timeout*)

Like **`sigwaitinfo()`**, but takes an additional *timeout* argument specifying a timeout. If *timeout* is specified as `0`, a poll is performed. Returns **`None`** if a timeout occurs.

Availability: Unix.

See the man page *sigtimedwait(2)* for further information.

See also **`pause()`**, **`sigwait()`** and **`sigwaitinfo()`**.

New in version 3.3.

Changed in version 3.5: The function is now retried with the recomputed *timeout* if interrupted by a signal not in *sigset* and the signal handler does not raise an exception (see **PEP 475** [https://peps.python.org/pep-0475/] for the rationale).

Examples

Here is a minimal example program. It uses the **`alarm()`** function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the **`os.open()`** to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```
import signal, os

def handler(signum, frame):
    signame = signal.Signals(signum).name
```

```
    print(f'Signal handler called with signal {signame}
    raise OSError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)          # Disable the alarm
```

Note on SIGPIPE

Piping output of your program to tools like *head(1)* will cause a **`SIGPIPE`** signal to be sent to your process when the receiver of its standard output closes early. This results in an exception like `BrokenPipeError: [Errno 32] Broken pipe`. To handle this case, wrap your entry point to catch this exception as follows:

```
import os
import sys

def main():
    try:
        # simulate large output (your code replaces this
        for x in range(10000):
            print("y")
        # flush output here to force SIGPIPE to be trigg
        # while inside this try block.
        sys.stdout.flush()
    except BrokenPipeError:
        # Python flushes standard streams on exit; redir
        # to devnull to avoid another BrokenPipeError at
        devnull = os.open(os.devnull, os.O_WRONLY)
        os.dup2(devnull, sys.stdout.fileno())
        sys.exit(1)  # Python exits with error code 1 or
```

```
if __name__ == '__main__':
    main()
```

Do not set **SIGPIPE**'s disposition to **SIG_DFL** in order to avoid **BrokenPipeError**. Doing that would cause your program to exit unexpectedly whenever any socket connection is interrupted while your program is still writing to it.

Note on Signal Handlers and Exceptions

If a signal handler raises an exception, the exception will be propagated to the main thread and may be raised after any bytecode instruction. Most notably, a **KeyboardInterrupt** may appear at any point during execution. Most Python code, including the standard library, cannot be made robust against this, and so a **KeyboardInterrupt** (or any other exception resulting from a signal handler) may on rare occasions put the program in an unexpected state.

To illustrate this issue, consider the following code:

```
class SpamContext:
    def __init__(self):
        self.lock = threading.Lock()

    def __enter__(self):
        # If KeyboardInterrupt occurs here, everything i
        self.lock.acquire()
        # If KeyboardInterrupt occurs here, __exit__ wil
        ...
        # KeyboardInterrupt could occur just before the

    def __exit__(self, exc_type, exc_val, exc_tb):
        ...
        self.lock.release()
```

For many programs, especially those that merely want to exit on **KeyboardInterrupt**, this is not a problem, but applications that are complex or require high reliability should avoid raising

exceptions from signal handlers. They should also avoid catching **`KeyboardInterrupt`** as a means of gracefully shutting down. Instead, they should install their own **`SIGINT`** handler. Below is an example of an HTTP server that avoids **`KeyboardInterrupt`**:

```
import signal
import socket
from selectors import DefaultSelector, EVENT_READ
from http.server import HTTPServer, SimpleHTTPRequestHar

interrupt_read, interrupt_write = socket.socketpair()

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    interrupt_write.send(b'\0')
signal.signal(signal.SIGINT, handler)

def serve_forever(httpd):
    sel = DefaultSelector()
    sel.register(interrupt_read, EVENT_READ)
    sel.register(httpd, EVENT_READ)

    while True:
        for key, _ in sel.select():
            if key.fileobj == interrupt_read:
                interrupt_read.recv(1)
                return
            if key.fileobj == httpd:
                httpd.handle_request()

print("Serving on port 8000")
httpd = HTTPServer(('', 8000), SimpleHTTPRequestHandler)
serve_forever(httpd)
print("Shutdown...")
```

`mmap` — Memory-mapped file support

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Memory-mapped file objects behave like both **`bytearray`** and like file objects. You can use mmap objects in most places where **`bytearray`** are expected; for example, you can use the **`re`** module to search through a memory-mapped file. You can also change a single byte by doing `obj[index] = 97`, or change a subsequence by assigning to a slice: `obj[i1:i2] = b'...'`. You can also read and write data starting at the current file position, and **`seek()`** through the file to different positions.

A memory-mapped file is created by the **`mmap`** constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its **`fileno()`** method to obtain the correct value for the *fileno* parameter. Otherwise, you can open the file using the **`os.open()`** function, which returns a file descriptor directly (the file still needs to be closed when done).

Note

If you want to create a memory-mapping for a writable, buffered file, you should **`flush()`** the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

For both the Unix and Windows versions of the constructor, *access* may be specified as an optional keyword parameter. *access* accepts one of four values: **ACCESS_READ**, **ACCESS_WRITE**, or **ACCESS_COPY** to specify read-only, write-through or copy-on-write memory respectively, or **ACCESS_DEFAULT** to defer to *prot*. *access* can be used on both Unix and Windows. If *access* is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an **ACCESS_READ** memory map raises a **TypeError** exception. Assignment to an **ACCESS_WRITE** memory map affects both memory and the underlying file. Assignment to an **ACCESS_COPY** memory map affects memory but does not update the underlying file.

Changed in version 3.7: Added **ACCESS_DEFAULT** constant.

To map anonymous memory, -1 should be passed as the fileno along with the length.

class mmap.mmap(*fileno*, *length*, *tagname*=*None*, *access*=*ACCESS_DEFAULT*[, *offset*])

(Windows version) Maps *length* bytes from the file specified by the file handle *fileno*, and creates a mmap object. If *length* is larger than the current size of the file, the file is extended to contain *length* bytes. If *length* is `0`, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

tagname, if specified and not `None`, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or `None`, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of

the file. *offset* defaults to 0. *offset* must be a multiple of the **ALLOCATIONGRANULARITY**.

Raises an auditing event `mmap.__new__` with arguments `fileno, length, access, offset`.

class mmap.mmap(*fileno*, *length*, *flags*=*MAP_SHARED*, *prot*=*PROT_WRITE*|*PROT_READ*, *access*=*ACCESS_DEFAULT*[, *offset*])

(Unix version) Maps *length* bytes from the file specified by the file descriptor *fileno*, and returns a mmap object. If *length* is `0`, the maximum length of the map will be the current size of the file when **mmap** is called.

flags specifies the nature of the mapping. **MAP_PRIVATE** creates a private copy-on-write mapping, so changes to the contents of the mmap object will be private to this process, and **MAP_SHARED** creates a mapping that's shared with all other processes mapping the same areas of the file. The default value is **MAP_SHARED**. Some systems have additional possible flags with the full list specified in MAP_* constants.

prot, if specified, gives the desired memory protection; the two most useful values are **PROT_READ** and **PROT_WRITE**, to specify that the pages may be read or written. *prot* defaults to **PROT_READ** | **PROT_WRITE**.

access may be specified in lieu of *flags* and *prot* as an optional keyword parameter. It is an error to specify both *flags*, *prot* and *access*. See the description of *access* above for information on how to use this parameter.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of **ALLOCATIONGRANULARITY** which is equal to **PAGESIZE** on Unix systems.

To ensure validity of the created memory mapping the file specified by the descriptor *fileno* is internally automatically

synchronized with the physical backing store on macOS.

This example shows a simple way of using **mmap**:

```
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
    f.write(b"Hello Python!\n")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print(mm.readline())  # prints b"Hello Python!\
    # read content via slice notation
    print(mm[:5])  # prints b"Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = b" world!\n"
    # ... and read again using standard file method
    mm.seek(0)
    print(mm.readline())  # prints b"Hello  world!\
    # close the map
    mm.close()
```

mmap can also be used as a context manager in a **with** statement:

```
import mmap

with mmap.mmap(-1, 13) as mm:
    mm.write(b"Hello world!")
```

New in version 3.2: Context manager support.

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```
import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write(b"Hello world!")

pid = os.fork()

if pid == 0:  # In a child process
    mm.seek(0)
    print(mm.readline())

    mm.close()
```

Raises an auditing event `mmap.__new__` with arguments `fileno`, `length`, `access`, `offset`.

Memory-mapped file objects support the following methods:

close()

Closes the mmap. Subsequent calls to other methods of the object will result in a ValueError exception being raised. This will not close the open file.

closed

`True` if the file is closed.

New in version 3.2.

find(*sub*[, *start*[, *end*]])

Returns the lowest index in the object where the subsequence *sub* is found, such that *sub* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns `-1` on failure.

Changed in version 3.5: Writable bytes-like object is now accepted.

flush([*offset*[, *size*]])

Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If *offset* and *size* are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed. *offset* must be a multiple of the **PAGESIZE** or **ALLOCATIONGRANULARITY**.

`None` is returned to indicate success. An exception is raised when the call failed.

Changed in version 3.8: Previously, a nonzero value was returned on success; zero was returned on error under Windows. A zero value was returned on success; an exception was raised on error under Unix.

madvise(*option*[, *start*[, *length*]])

Send advice *option* to the kernel about the memory region beginning at *start* and extending *length* bytes. *option* must be one of the MADV_* constants available on the system. If *start* and *length* are omitted, the entire mapping is spanned. On some systems (including Linux), *start* must be a multiple of the **PAGESIZE**.

Availability: Systems with the `madvise()` system call.

New in version 3.8.

move(*dest*, *src*, *count*)

Copy the *count* bytes starting at offset *src* to the destination index *dest*. If the mmap was created with **ACCESS_READ**, then calls to move will raise a **TypeError** exception.

read([*n*])

Return a **bytes** containing up to *n* bytes starting from

the current file position. If the argument is omitted, `None` or negative, return all bytes from the current file position to the end of the mapping. The file position is updated to point after the bytes that were returned.

Changed in version 3.3: Argument can be omitted or `None`.

read_byte()

Returns a byte at the current file position as an integer, and advances the file position by 1.

readline()

Returns a single line, starting at the current file position and up to the next newline. The file position is updated to point after the bytes that were returned.

resize(*newsize*)

Resizes the map and the underlying file, if any. If the mmap was created with **`ACCESS_READ`** or **`ACCESS_COPY`**, resizing the map will raise a **`TypeError`** exception.

On Windows: Resizing the map will raise an **`OSError`** if there are other maps against the same named file. Resizing an anonymous map (ie against the pagefile) will silently create a new map with the original data copied over up to the length of the new size.

Changed in version 3.11: Correctly fails if attempting to resize when another map is held Allows resize against an anonymous map on Windows

rfind(*sub*[, *start*[, *end*]])

Returns the highest index in the object where the subsequence *sub* is found, such that *sub* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns `-1` on

failure.

Changed in version 3.5: Writable bytes-like object is now accepted.

seek(*pos*[, *whence*])

Set the file's current position. *whence* argument is optional and defaults to `os.SEEK_SET` or `0` (absolute file positioning); other values are `os.SEEK_CUR` or `1` (seek relative to the current position) and `os.SEEK_END` or `2` (seek relative to the file's end).

size()

Return the length of the file, which can be larger than the size of the memory-mapped area.

tell()

Returns the current position of the file pointer.

write(*bytes*)

Write the bytes in *bytes* into memory at the current position of the file pointer and return the number of bytes written (never less than `len(bytes)`, since if the write fails, a **`ValueError`** will be raised). The file position is updated to point after the bytes that were written. If the mmap was created with **`ACCESS_READ`**, then writing to it will raise a **`TypeError`** exception.

Changed in version 3.5: Writable bytes-like object is now accepted.

Changed in version 3.6: The number of bytes written is now returned.

write_byte(*byte*)

Write the integer *byte* into memory at the current position of the file pointer; the file position is advanced by `1`. If the mmap was created with **`ACCESS_READ`**,

then writing to it will raise a **TypeError** exception.

MADV_* Constants

mmap.MADV_NORMAL
mmap.MADV_RANDOM
mmap.MADV_SEQUENTIAL
mmap.MADV_WILLNEED
mmap.MADV_DONTNEED
mmap.MADV_REMOVE
mmap.MADV_DONTFORK
mmap.MADV_DOFORK
mmap.MADV_HWPOISON
mmap.MADV_MERGEABLE
mmap.MADV_UNMERGEABLE
mmap.MADV_SOFT_OFFLINE
mmap.MADV_HUGEPAGE
mmap.MADV_NOHUGEPAGE
mmap.MADV_DONTDUMP
mmap.MADV_DODUMP
mmap.MADV_FREE
mmap.MADV_NOSYNC
mmap.MADV_AUTOSYNC
mmap.MADV_NOCORE
mmap.MADV_CORE
mmap.MADV_PROTECT
mmap.MADV_FREE_REUSABLE
mmap.MADV_FREE_REUSE

These options can be passed to **mmap.madvise()**. Not every option will be present on every system.

Availability: Systems with the madvise() system call.

New in version 3.8.

MAP_* Constants

mmap.MAP_SHARED
mmap.MAP_PRIVATE

mmap.MAP_DENYWRITE
mmap.MAP_EXECUTABLE
mmap.MAP_ANON
mmap.MAP_ANONYMOUS
mmap.MAP_POPULATE
mmap.MAP_STACK

These are the various flags that can be passed to **`mmap.mmap()`**. Note that some options might not be present on some systems.

Changed in version 3.10: Added MAP_POPULATE constant.

New in version 3.11: Added MAP_STACK constant.

Internet Data Handling

This chapter describes modules which support handling data formats commonly used on the internet.

- **email** — An email and MIME handling package
  - **email.message**: Representing an email message
  - **email.parser**: Parsing email messages
    - FeedParser API
    - Parser API
    - Additional notes
  - **email.generator**: Generating MIME documents
  - **email.policy**: Policy Objects
  - **email.errors**: Exception and Defect classes
  - **email.headerregistry**: Custom Header Objects
  - **email.contentmanager**: Managing MIME Content
    - Content Manager Instances
  - **email**: Examples
  - **email.message.Message**: Representing an email message using the **compat32** API
  - **email.mime**: Creating email and MIME objects from scratch
  - **email.header**: Internationalized headers
  - **email.charset**: Representing character sets
  - **email.encoders**: Encoders
  - **email.utils**: Miscellaneous utilities
  - **email.iterators**: Iterators
- **json** — JSON encoder and decoder
  - Basic Usage
  - Encoders and Decoders

    - Exceptions
    - Standard Compliance and Interoperability
        - Character Encodings
        - Infinite and NaN Number Values
        - Repeated Names Within an Object
        - Top-level Non-Object, Non-Array Values
        - Implementation Limitations
    - Command Line Interface
        - Command line options
- **mailbox** — Manipulate mailboxes in various formats
    - **Mailbox** objects
        - **Maildir**
        - **mbox**
        - **MH**
        - **Babyl**
        - **MMDF**
    - **Message** objects
        - **MaildirMessage**
        - **mboxMessage**
        - **MHMessage**
        - **BabylMessage**
        - **MMDFMessage**
    - Exceptions
    - Examples
- **mimetypes** — Map filenames to MIME types
    - MimeTypes Objects
- **base64** — Base16, Base32, Base64, Base85 Data Encodings
    - Security Considerations

- **`binascii`** — Convert between binary and ASCII
- **`quopri`** — Encode and decode MIME quoted-printable data

`email` — An email and MIME handling package

Source code: Lib/email/__init__.py [https://github.com/python/cpython/tree/3.11/Lib/email/__init__.py]

The `email` package is a library for managing email messages. It is specifically *not* designed to do any sending of email messages to SMTP (**RFC 2821** [https://datatracker.ietf.org/doc/html/rfc2821.html]), NNTP, or other servers; those are functions of modules such as `smtplib` and `nntplib`. The `email` package attempts to be as RFC-compliant as possible, supporting **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] and **RFC 6532** [https://datatracker.ietf.org/doc/html/rfc6532.html], as well as such MIME-related RFCs as **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html], **RFC 2046** [https://datatracker.ietf.org/doc/html/rfc2046.html], **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html], **RFC 2183** [https://datatracker.ietf.org/doc/html/rfc2183.html], and **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html].

The overall structure of the email package can be divided into three major components, plus a fourth component that controls the behavior of the other components.

The central component of the package is an “object model” that represents email messages. An application interacts with the package primarily through the object model interface defined in the `message` sub-module. The application can use this API to ask questions about an existing email, to construct a new email, or to add or remove email subcomponents that themselves use the same object model interface. That is, following the nature of email messages and their MIME subcomponents, the email object model is a tree structure of objects that all provide the `EmailMessage` API.

The other two major components of the package are the `parser`

and the **generator**. The parser takes the serialized version of an email message (a stream of bytes) and converts it into a tree of **EmailMessage** objects. The generator takes an **EmailMessage** and turns it back into a serialized byte stream. (The parser and generator also handle streams of text characters, but this usage is discouraged as it is too easy to end up with messages that are not valid in one way or another.)

The control component is the **policy** module. Every **EmailMessage**, every **generator**, and every **parser** has an associated **policy** object that controls its behavior. Usually an application only needs to specify the policy when an **EmailMessage** is created, either by directly instantiating an **EmailMessage** to create a new email, or by parsing an input stream using a **parser**. But the policy can be changed when the message is serialized using a **generator**. This allows, for example, a generic email message to be parsed from disk, but to serialize it using standard SMTP settings when sending it to an email server.

The email package does its best to hide the details of the various governing RFCs from the application. Conceptually the application should be able to treat the email message as a structured tree of unicode text and binary attachments, without having to worry about how these are represented when serialized. In practice, however, it is often necessary to be aware of at least some of the rules governing MIME messages and their structure, specifically the names and nature of the MIME “content types” and how they identify multipart documents. For the most part this knowledge should only be required for more complex applications, and even then it should only be the high level structure in question, and not the details of how those structures are represented. Since MIME content types are used widely in modern internet software (not just email), this will be a familiar concept to many programmers.

The following sections describe the functionality of the **email** package. We start with the **message** object model, which is the primary interface an application will use, and follow that with the **parser** and **generator** components. Then we cover the **policy** controls, which completes the treatment of the main components of the library.

The next three sections cover the exceptions the package may raise and the defects (non-compliance with the RFCs) that the **parser** may detect. Then we cover the **headerregistry** and the **contentmanager** sub-components, which provide tools for doing more detailed manipulation of headers and payloads, respectively. Both of these components contain features relevant to consuming and producing non-trivial messages, but also document their extensibility APIs, which will be of interest to advanced applications.

Following those is a set of examples of using the fundamental parts of the APIs covered in the preceding sections.

The foregoing represent the modern (unicode friendly) API of the email package. The remaining sections, starting with the **Message** class, cover the legacy **compat32** API that deals much more directly with the details of how email messages are represented. The **compat32** API does *not* hide the details of the RFCs from the application, but for applications that need to operate at that level, they can be useful tools. This documentation is also relevant for applications that are still using the **compat32** API for backward compatibility reasons.

Changed in version 3.6: Docs reorganized and rewritten to promote the new **EmailMessage**/**EmailPolicy** API.

Contents of the **email** package documentation:

- **email.message**: Representing an email message
- **email.parser**: Parsing email messages
    - FeedParser API
    - Parser API
    - Additional notes
- **email.generator**: Generating MIME documents
- **email.policy**: Policy Objects
- **email.errors**: Exception and Defect classes
- **email.headerregistry**: Custom Header Objects
- **email.contentmanager**: Managing MIME Content

    - Content Manager Instances

- **email**: Examples

Legacy API:

- **email.message.Message**: Representing an email message using the **compat32** API
- **email.mime**: Creating email and MIME objects from scratch
- **email.header**: Internationalized headers
- **email.charset**: Representing character sets
- **email.encoders**: Encoders
- **email.utils**: Miscellaneous utilities
- **email.iterators**: Iterators

`email.message`: Representing an email message

Source code: Lib/email/message.py [https://github.com/python/cpython/tree/3.11/Lib/email/message.py]

New in version 3.6: 1

The central class in the `email` package is the `EmailMessage` class, imported from the `email.message` module. It is the base class for the `email` object model. `EmailMessage` provides the core functionality for setting and querying header fields, for accessing message bodies, and for creating or modifying structured messages.

An email message consists of *headers* and a *payload* (which is also referred to as the *content*). Headers are **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] or **RFC 6532** [https://datatracker.ietf.org/doc/html/rfc6532.html] style field names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as *multipart/** or *message/rfc822*.

The conceptual model provided by an `EmailMessage` object is that of an ordered dictionary of headers coupled with a *payload* that represents the **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] body of the message, which might be a list of sub-`EmailMessage` objects. In addition to the normal dictionary methods for accessing the header names and values, there are methods for accessing specialized information from the headers (for example the MIME content type), for operating on the payload, for generating a serialized version of the message, and for recursively walking over

the object tree.

The **EmailMessage** dictionary-like interface is indexed by the header names, which must be ASCII values. The values of the dictionary are strings with some extra methods. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. Unlike a real dict, there is an ordering to the keys, and there can be duplicate keys. Additional methods are provided for working with headers that have duplicate keys.

The *payload* is either a string or bytes object, in the case of simple message objects, or a list of **EmailMessage** objects, for MIME container documents such as *multipart/** and *message/rfc822* message objects.

class email.message.EmailMessage(*policy*=*default*)

If *policy* is specified use the rules it specifies to update and serialize the representation of the message. If *policy* is not set, use the **default** policy, which follows the rules of the email RFCs except for line endings (instead of the RFC mandated `\r\n`, it uses the Python standard `\n` line endings). For more information see the **policy** documentation.

as_string(*unixfrom*=*False*, *maxheaderlen*=*None*, *policy*=*None*)

Return the entire message flattened as a string. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. For backward compatibility with the base **Message** class *maxheaderlen* is accepted, but defaults to `None`, which means that by default the line length is controlled by the **max_line_length** of the policy. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the **Generator**.

Flattening the message may trigger changes to the **EmailMessage** if defaults need to be filled in to complete the transformation to a string (for example,

MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See **email.generator.Generator** for a more flexible API for serializing messages. Note also that this method is restricted to producing messages serialized as "7 bit clean" when **utf8** is `False`, which is the default.

Changed in version 3.6: the default behavior when *maxheaderlen* is not specified was changed from defaulting to 0 to defaulting to the value of *max_line_length* from the policy.

__str__()

Equivalent to `as_string(policy=self.policy.clone(utf8=True))`. Allows `str(msg)` to produce a string containing the serialized message in a readable format.

Changed in version 3.4: the method was changed to use `utf8=True`, thus producing an **RFC 6531** [https://datatracker.ietf.org/doc/html/rfc6531.html]-like message representation, instead of being a direct alias for **as_string()**.

as_bytes(*unixfrom=False*, *policy=None*)

Return the entire message flattened as a bytes object. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the **BytesGenerator**.

Flattening the message may trigger changes to the

EmailMessage if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See **email.generator.BytesGenerator** for a more flexible API for serializing messages.

bytes()

Equivalent to **as_bytes()**. Allows `bytes(msg)` to produce a bytes object containing the serialized message.

is_multipart()

Return `True` if the message's payload is a list of sub-**EmailMessage** objects, otherwise return `False`. When **is_multipart()** returns `False`, the payload should be a string object (which might be a CTE encoded binary payload). Note that **is_multipart()** returning `True` does not necessarily mean that "msg.get_content_maintype() == 'multipart'" will return the `True`. For example, `is_multipart` will return `True` when the **EmailMessage** is of type `message/rfc822`.

set_unixfrom(*unixfrom*)

Set the message's envelope header to *unixfrom*, which should be a string. (See **mboxMessage** for a brief description of this header.)

get_unixfrom()

Return the message's envelope header. Defaults to `None` if the envelope header was never set.

The following methods implement the mapping-like interface

for accessing the message's headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by **`keys()`**, but in an **`EmailMessage`** object, headers are always returned in the order they appeared in the original message, or in which they were added to the message later. Any header deleted and then re-added is always appended to the end of the header list.

These semantic differences are intentional and are biased toward convenience in the most common use cases.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

len()

Return the total number of headers, including duplicates.

contains(*name*)

Return `True` if the message object has a field named *name*. Matching is done without regard to case and *name* does not include the trailing colon. Used for the `in` operator. For example:

```
if 'message-id' in myMessage:
   print('Message-ID:', myMessage['message-id']
```

getitem(*name*)

Return the value of the named header field. *name* does not include the colon field separator. If the header is missing, `None` is returned; a **`KeyError`** is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field

values will be returned is undefined. Use the **get_all()** method to get the values of all the extant headers named *name*.

Using the standard (non-compat32) policies, the returned value is an instance of a subclass of **email.headerregistry.BaseHeader**.

setitem(*name*, *val*)

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing headers.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

If the **policy** defines certain headers to be unique (as the standard policies do), this method may raise a **ValueError** when an attempt is made to assign a value to such a header when one already exists. This behavior is intentional for consistency's sake, but do not depend on it as we may choose to make such assignments do an automatic deletion of the existing header in the future.

delitem(*name*)

Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

keys()

Return a list of all the message's header field names.

values()

Return a list of all the message's field values.

items()

Return a list of 2-tuples containing all the message's field headers and values.

get(*name*, *failobj*=*None*)

Return the value of the named header field. This is identical to `__getitem__()` except that optional *failobj* is returned if the named header is missing (*failobj* defaults to `None`).

Here are some additional useful header related methods:

get_all(*name*, *failobj*=*None*)

Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to `None`).

add_header(*_name*, *_value*, ***_params*)

Extended header setting. This method is similar to `__setitem__()` except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as `key="value"` unless the value is `None`, in which case only the key will be added.

If the value contains non-ASCII characters, the charset and language may be explicitly controlled by specifying the value as a three tuple in the format `(CHARSET, LANGUAGE, VALUE)`, where `CHARSET` is a string naming the charset to be used to encode the value,

`LANGUAGE` can usually be set to `None` or the empty string (see **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html] for other possibilities), and `VALUE` is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html] format using a `CHARSET` of `utf-8` and a `LANGUAGE` of `None`.

Here is an example:

```
msg.add_header('Content-Disposition', 'attachme
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.
```

An example of the extended interface with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachme
               filename=('iso-8859-1', '', 'Fuf
```

replace_header(*_name*, *_value*)

Replace a header. Replace the first header found in the message that matches *_name*, retaining header order and field name case of the original header. If no matching header is found, raise a **`KeyError`**.

get_content_type()

Return the message's content type, coerced to lower case of the form *maintype/subtype*. If there is no *Content-Type* header in the message return the value returned by **`get_default_type()`**. If the *Content-Type* header is invalid, return `text/plain`.

(According to **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html], messages always have a default type, **`get_content_type()`** will always return a value.

RFC 2045 [https://datatracker.ietf.org/doc/html/rfc2045.html] defines a message's default type to be *text/plain* unless it appears inside a *multipart/digest* container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html] mandates that the default type be *text/plain*.)

get_content_maintype()

Return the message's main content type. This is the *maintype* part of the string returned by **`get_content_type()`**.

get_content_subtype()

Return the message's sub-content type. This is the *subtype* part of the string returned by **`get_content_type()`**.

get_default_type()

Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

set_default_type(*ctype*)

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header, so it only affects the return value of the `get_content_type` methods when no *Content-Type* header is present in the message.

set_param(*param*, *value*, *header*='Content-Type', *requote*=*True*, *charset*=*None*, *language*='', *replace*=*False*)

Set a parameter in the *Content-Type* header. If the parameter already exists in the header, replace its value with *value*. When *header* is `Content-Type` (the

default) and the header does not yet exist in the message, add it, set its value to *text/plain*, and append the new parameter value. Optional *header* specifies an alternative header to *Content-Type*.

If the value contains non-ASCII characters, the charset and language may be explicitly specified using the optional *charset* and *language* parameters. Optional *language* specifies the **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html] language, defaulting to the empty string. Both *charset* and *language* should be strings. The default is to use the `utf8` *charset* and `None` for the *language*.

If *replace* is `False` (the default) the header is moved to the end of the list of headers. If *replace* is `True`, the header will be updated in place.

Use of the *requote* parameter with **`EmailMessage`** objects is deprecated.

Note that existing parameter values of headers may be accessed through the **`params`** attribute of the header value (for example, `msg['Content-Type'].params['charset']`).

Changed in version 3.4: `replace` keyword was added.

del_param(*param*, *header*=*'content-type'*, *requote*=*True*)

Remove the given parameter completely from the *Content-Type* header. The header will be re-written in place without the parameter or its value. Optional *header* specifies an alternative to *Content-Type*.

Use of the *requote* parameter with **`EmailMessage`** objects is deprecated.

get_filename(*failobj*=*None*)

Return the value of the `filename` parameter of the *Content-Disposition* header of the message. If the header

does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per **`email.utils.unquote()`**.

get_boundary(*failobj* = *None*)

Return the value of the `boundary` parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per **`email.utils.unquote()`**.

set_boundary(*boundary*)

Set the `boundary` parameter of the *Content-Type* header to *boundary*. **`set_boundary()`** will always quote *boundary* if necessary. A **`HeaderParseError`** is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different from deleting the old *Content-Type* header and adding a new one with the new boundary via **`add_header()`**, because **`set_boundary()`** preserves the order of the *Content-Type* header in the list of headers.

get_content_charset(*failobj* = *None*)

Return the `charset` parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no `charset` parameter, *failobj* is returned.

get_charsets(*failobj* = *None*)

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the *Content-Type* header for the represented subpart. If the subpart has no *Content-Type* header, no `charset` parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

is_attachment()

Return `True` if there is a *Content-Disposition* header and its (case insensitive) value is `attachment`, `False` otherwise.

Changed in version 3.4.2: is_attachment is now a method instead of a property, for consistency with **`is_multipart()`**.

get_content_disposition()

Return the lowercased value (without parameters) of the message's *Content-Disposition* header if it has one, or `None`. The possible values for this method are *inline*, *attachment* or `None` if the message follows **RFC 2183** [https://datatracker.ietf.org/doc/html/rfc2183.html].

New in version 3.5.

The following methods relate to interrogating and manipulating the content (payload) of the message.

walk()

The **`walk()`** method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use **`walk()`** as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```
>>> for part in msg.walk():
```

```
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```

`walk` iterates over the subparts of any part where **`is_multipart()`** returns `True`, even though `msg.get_content_maintype() == 'multipart'` may return `False`. We can see this in our example by making use of the `_structure` debug helper function:

```
>>> from email.iterators import _structure
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'm
...           part.is_multipart())
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
    text/plain
    message/delivery-status
        text/plain
        text/plain
    message/rfc822
        text/plain
```

Here the `message` parts are not `multiparts`, but they do contain subparts. `is_multipart()` returns `True` and `walk` descends into the subparts.

get_body(*preferencelist=('related', 'html', 'plain')*)

Return the MIME part that is the best candidate to be the "body" of the message.

preferencelist must be a sequence of strings from the set `related`, `html`, and `plain`, and indicates the order of preference for the content type of the part returned.

Start looking for candidate matches with the object on which the `get_body` method is called.

If `related` is not included in *preferencelist*, consider the root part (or subpart of the root part) of any related encountered as a candidate if the (sub-)part matches a preference.

When encountering a `multipart/related`, check the `start` parameter and if a part with a matching *Content-ID* is found, consider only it when looking for candidate matches. Otherwise consider only the first (default root) part of the `multipart/related`.

If a part has a *Content-Disposition* header, only consider the part a candidate match if the value of the header is `inline`.

If none of the candidates matches any of the preferences in *preferencelist*, return `None`.

Notes: (1) For most applications the only *preferencelist* combinations that really make sense are `('plain',)`, `('html', 'plain')`, and the default `('related', 'html', 'plain')`. (2) Because matching starts with the object on which `get_body` is called, calling `get_body` on a `multipart/related` will return the object itself unless *preferencelist* has a non-default value. (3) Messages (or message parts) that do not specify a *Content-Type* or whose *Content-Type* header is invalid will be treated as if they are of type `text/plain`, which may occasionally cause `get_body` to return unexpected results.

iter_attachments()

Return an iterator over all of the immediate sub-parts of the message that are not candidate "body" parts. That is, skip the first occurrence of each of `text/plain`, `text/html`, `multipart/related`, or `multipart/alternative` (unless they are explicitly marked as attachments via *Content-Disposition: attachment*), and return all remaining parts. When applied directly to a `multipart/related`, return an iterator over the all the related parts except the root part (ie: the part pointed to by the `start` parameter, or the first part if there is no `start` parameter or the `start` parameter doesn't match the *Content-ID* of any of the parts). When applied directly to a `multipart/alternative` or a non-`multipart`, return an empty iterator.

iter_parts()

Return an iterator over all of the immediate sub-parts of the message, which will be empty for a non-`multipart`. (See also **`walk()`**.)

get_content(**args*, *content_manager=None*, ***kw*)

Call the **`get_content()`** method of the *content_manager*, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If *content_manager* is not specified, use the `content_manager` specified by the current **`policy`**.

set_content(**args*, *content_manager=None*, ***kw*)

Call the **`set_content()`** method of the *content_manager*, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If *content_manager* is not specified, use the `content_manager` specified by the current **`policy`**.

make_related(*boundary*=*None*)

Convert a non-`multipart` message into a `multipart/related` message, moving any existing *Content-* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_alternative(*boundary*=*None*)

Convert a non-`multipart` or a `multipart/related` into a `multipart/alternative`, moving any existing *Content-* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_mixed(*boundary*=*None*)

Convert a non-`multipart`, a `multipart/related`, or a `multipart-alternative` into a `multipart/mixed`, moving any existing *Content-* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

add_related(**args*, *content_manager*=*None*, ***kw*)

If the message is a `multipart/related`, create a new message object, pass all of the arguments to its **`set_content()`** method, and **`attach()`** it to the `multipart`. If the message is a non-`multipart`, call **`make_related()`** and then proceed as above. If the message is any other type of `multipart`, raise a **`TypeError`**. If *content_manager* is not specified, use the `content_manager` specified by the current **`policy`**. If the added part has no *Content-Disposition* header, add

one with the value `inline`.

add_alternative(**args*, *content_manager=None*, ***kw*)

If the message is a `multipart/alternative`, create a new message object, pass all of the arguments to its **`set_content()`** method, and **`attach()`** it to the `multipart`. If the message is a non-`multipart` or `multipart/related`, call **`make_alternative()`** and then proceed as above. If the message is any other type of `multipart`, raise a **`TypeError`**. If *content_manager* is not specified, use the `content_manager` specified by the current **`policy`**.

add_attachment(**args*, *content_manager=None*, ***kw*)

If the message is a `multipart/mixed`, create a new message object, pass all of the arguments to its **`set_content()`** method, and **`attach()`** it to the `multipart`. If the message is a non-`multipart`, `multipart/related`, or `multipart/alternative`, call **`make_mixed()`** and then proceed as above. If *content_manager* is not specified, use the `content_manager` specified by the current **`policy`**. If the added part has no *Content-Disposition* header, add one with the value `attachment`. This method can be used both for explicit attachments (*Content-Disposition: attachment*) and `inline` attachments (*Content-Disposition: inline*), by passing appropriate options to the `content_manager`.

clear()

Remove the payload and all of the headers.

clear_content()

Remove the payload and all of the **`Content-`** headers, leaving all other headers intact and in their original order.

`EmailMessage` objects have the following instance

attributes:

preamble

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the **`Parser`** discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the **`Generator`** is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See **`email.parser`** and **`email.generator`** for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

epilogue

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message. As with the **`preamble`**, if there is no epilog text this attribute will be `None`.

defects

The *defects* attribute contains a list of all the problems found when parsing this message. See **`email.errors`** for a detailed description of the possible parsing defects.

class email.message.MIMEPart(*policy* = *default*)

This class represents a subpart of a MIME message. It is identical to `EmailMessage`, except that no *MIME-Version* headers are added when `set_content()` is called, since sub-parts do not need their own *MIME-Version* headers.

Footnotes

1

Originally added in 3.4 as a provisional module. Docs for legacy message class moved to email.message.Message: Representing an email message using the compat32 API.

email.parser: Parsing email messages

Source code: Lib/email/parser.py [https://github.com/python/cpython/tree/3.11/Lib/email/parser.py]

Message object structures can be created in one of two ways: they can be created from whole cloth by creating an `EmailMessage` object, adding headers using the dictionary interface, and adding payload(s) using `set_content()` and related methods, or they can be created by parsing a serialized representation of the email message.

The `email` package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a bytes, string or file object, and the parser will return to you the root `EmailMessage` instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return `True` from its `is_multipart()` method, and the subparts can be accessed via the payload manipulation methods, such as `get_body()`, `iter_parts()`, and `walk()`.

There are actually two parser interfaces available for use, the `Parser` API and the incremental `FeedParser` API. The `Parser` API is most useful if you have the entire text of the message in memory, or if the entire message lives in a file on the file system. `FeedParser` is more appropriate when you are reading the message from a stream which might block waiting for more input (such as reading an email message from a socket). The `FeedParser` can consume and parse the message incrementally, and only returns the root object when you close the parser.

Note that the parser can be extended in limited ways, and of course

you can implement your own parser completely from scratch. All of the logic that connects the **email** package's bundled parser and the **EmailMessage** class is embodied in the **policy** class, so a custom parser can create message object trees any way it finds necessary by implementing custom versions of the appropriate **policy** methods.

FeedParser API

The **BytesFeedParser**, imported from the **email.feedparser** module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (such as a socket). The **BytesFeedParser** can of course be used to parse an email message fully contained in a bytes-like object, string, or file, but the **BytesParser** API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The **BytesFeedParser**'s API is simple; you create an instance, feed it a bunch of bytes until there's no more to feed it, then close the parser to retrieve the root message object. The **BytesFeedParser** is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object's **defects** attribute with a list of any problems it found in a message. See the **email.errors** module for the list of defects that it can find.

Here is the API for the **BytesFeedParser**:

class email.parser.BytesFeedParser(*_factory=None*, *, *policy=policy.compat32*)

Create a **BytesFeedParser** instance. Optional *_factory* is a no-argument callable; if not specified use the **message_factory** from the *policy*. Call *_factory* whenever a new message object is needed.

If *policy* is specified use the rules it specifies to update the representation of the message. If *policy* is not set, use the

compat32 policy, which maintains backward compatibility with the Python 3.2 version of the email package and provides **Message** as the default factory. All other policies provide **EmailMessage** as the default *_factory*. For more information on what else *policy* controls, see the **policy** documentation.

Note: **The policy keyword should always be specified**; The default will change to **email.policy.default** in a future version of Python.

New in version 3.2.

Changed in version 3.3: Added the *policy* keyword.

Changed in version 3.6: *_factory* defaults to the policy `message_factory`.

feed(*data*)

Feed the parser some more data. *data* should be a bytes-like object containing one or more lines. The lines can be partial and the parser will stitch such partial lines together properly. The lines can have any of the three common line endings: carriage return, newline, or carriage return and newline (they can even be mixed).

close()

Complete the parsing of all previously fed data and return the root message object. It is undefined what happens if **feed()** is called after this method has been called.

class email.parser.FeedParser(*_factory=None*, *, *policy=policy.compat32*)

Works like **BytesFeedParser** except that the input to the **feed()** method must be a string. This is of limited utility, since the only way for such a message to be valid is for it to contain only ASCII text or, if **utf8** is `True`, no binary attachments.

Changed in version 3.3: Added the *policy* keyword.

Parser API

The **BytesParser** class, imported from the **email.parser** module, provides an API that can be used to parse a message when the complete contents of the message are available in a bytes-like object or file. The **email.parser** module also provides **Parser** for parsing strings, and header-only parsers, **BytesHeaderParser** and **HeaderParser**, which can be used if you're only interested in the headers of the message. **BytesHeaderParser** and **HeaderParser** can be much faster in these situations, since they do not attempt to parse the message body, instead setting the payload to the raw body.

class email.parser.BytesParser(*_class=None*, ***, *policy=policy.compat32*)

Create a **BytesParser** instance. The *_class* and *policy* arguments have the same meaning and semantics as the *_factory* and *policy* arguments of **BytesFeedParser**.

Note: **The policy keyword should always be specified**; The default will change to **email.policy.default** in a future version of Python.

Changed in version 3.3: Removed the *strict* argument that was deprecated in 2.4. Added the *policy* keyword.

Changed in version 3.6: *_class* defaults to the policy `message_factory`.

parse(*fp*, *headersonly=False*)

Read all the data from the binary file-like object *fp*, parse the resulting bytes, and return the message object. *fp* must support both the **readline()** and the **read()** methods.

The bytes contained in *fp* must be formatted as a block of **RFC 5322** [https://datatracker.ietf.org/doc/html/

rfc5322.html] (or, if **utf8** is `True`, **RFC 6532** [https://datatracker.ietf.org/doc/html/rfc6532.html]) style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts, including subparts with a *Content-Transfer-Encoding* of `8bit`).

Optional *headersonly* is a flag specifying whether to stop parsing after reading the headers or not. The default is `False`, meaning it parses the entire contents of the file.

parsebytes(*bytes*, *headersonly*=*False*)

Similar to the **parse()** method, except it takes a bytes-like object instead of a file-like object. Calling this method on a bytes-like object is equivalent to wrapping *bytes* in a **BytesIO** instance first and calling **parse()**.

Optional *headersonly* is as with the **parse()** method.

New in version 3.2.

class email.parser.BytesHeaderParser(*_class*=*None*, *, *policy*=*policy.compat32*)

Exactly like **BytesParser**, except that *headersonly* defaults to `True`.

New in version 3.3.

class email.parser.Parser(*_class*=*None*, *, *policy*=*policy.compat32*)

This class is parallel to **BytesParser**, but handles string input.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

Changed in version 3.6: _class defaults to the policy

`message_factory`.

parse(*fp*, *headersonly*=*False*)

Read all the data from the text-mode file-like object *fp*, parse the resulting text, and return the root message object. *fp* must support both the **`readline()`** and the **`read()`** methods on file-like objects.

Other than the text mode requirement, this method operates like **`BytesParser.parse()`**.

parsestr(*text*, *headersonly*=*False*)

Similar to the **`parse()`** method, except it takes a string object instead of a file-like object. Calling this method on a string is equivalent to wrapping *text* in a **`StringIO`** instance first and calling **`parse()`**.

Optional *headersonly* is as with the **`parse()`** method.

class email.parser.HeaderParser(*_class*=*None*, ***, *policy*=*policy.compat32*)

Exactly like **`Parser`**, except that *headersonly* defaults to `True`.

Since creating a message object structure from a string or a file object is such a common task, four functions are provided as a convenience. They are available in the top-level **`email`** package namespace.

email.message_from_bytes(*s*, *_class*=*None*, ***, *policy*=*policy.compat32*)

Return a message object structure from a bytes-like object. This is equivalent to `BytesParser().parsebytes(s)`. Optional *_class* and *policy* are interpreted as with the **`BytesParser`** class constructor.

New in version 3.2.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

email.message_from_binary_file(*fp*, *_class=None*, *, *policy=policy.compat32*)

Return a message object structure tree from an open binary file object. This is equivalent to `BytesParser().parse(fp)`. *_class* and *policy* are interpreted as with the **`BytesParser`** class constructor.

New in version 3.2.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

email.message_from_string(*s*, *_class=None*, *, *policy=policy.compat32*)

Return a message object structure from a string. This is equivalent to `Parser().parsestr(s)`. *_class* and *policy* are interpreted as with the **`Parser`** class constructor.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

email.message_from_file(*fp*, *_class=None*, *, *policy=policy.compat32*)

Return a message object structure tree from an open file object. This is equivalent to `Parser().parse(fp)`. *_class* and *policy* are interpreted as with the **`Parser`** class constructor.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

Changed in version 3.6: *_class* defaults to the policy `message_factory`.

Here's an example of how you might use **`message_from_bytes()`** at an interactive Python prompt:

```
>>> import email
>>> msg = email.message_from_bytes(myBytes)
```

Additional notes

Here are some notes on the parsing semantics:

- Most non-*multipart* type messages are parsed as a single message object with a string payload. These objects will return `False` for **`is_multipart()`**, and **`iter_parts()`** will yield an empty list.
- All *multipart* type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return `True` for **`is_multipart()`**, and **`iter_parts()`** will yield a list of subparts.
- Most messages with a content type of *message/** (such as *message/delivery-status* and *message/rfc822*) will also be parsed as container object containing a list payload of length 1. Their **`is_multipart()`** method will return `True`. The single element yielded by **`iter_parts()`** will be a sub-message object.
- Some non-standards-compliant messages may not be internally consistent about their *multipart*-edness. Such messages may have a *Content-Type* header of type *multipart*, but their **`is_multipart()`** method may return `False`. If such messages were parsed with the **`FeedParser`**, they will have an instance of the **`MultipartInvariantViolationDefect`** class in their *defects* attribute list. See **`email.errors`** for details.

`email.generator`: Generating MIME documents

Source code: Lib/email/generator.py [https://github.com/python/cpython/tree/3.11/Lib/email/generator.py]

One of the most common tasks is to generate the flat (serialized) version of the email message represented by a message object structure. You will need to do this if you want to send your message via `smtplib.SMTP.sendmail()` or the `nntplib` module, or print the message on the console. Taking a message object structure and producing a serialized representation is the job of the generator classes.

As with the `email.parser` module, you aren't limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the bytes-oriented parsing and generation operations are inverses, assuming the same non-transforming `policy` is used for both. That is, parsing the serialized byte stream via the `BytesParser` class and then regenerating the serialized byte stream using `BytesGenerator` should produce output identical to the input [1]. (On the other hand, using the generator on an `EmailMessage` constructed by program may result in changes to the `EmailMessage` object as defaults are filled in.)

The `Generator` class can be used to flatten a message into a text (as opposed to binary) serialized representation, but since Unicode cannot represent binary data directly, the message is of necessity transformed into something that contains only ASCII characters, using the standard email RFC Content Transfer Encoding techniques for encoding email messages for transport over channels that are not "8 bit clean".

To accommodate reproducible processing of SMIME-signed messages **`Generator`** disables header folding for message parts of type `multipart/signed` and all subparts.

class email.generator.BytesGenerator(*outfp*, *mangle_from_* = *None*, *maxheaderlen* = *None*, ***, *policy* = *None*)

Return a **`BytesGenerator`** object that will write any message provided to the **`flatten()`** method, or any surrogateescape encoded text provided to the **`write()`** method, to the file-like object *outfp*. *outfp* must support a `write` method that accepts binary data.

If optional *mangle_from_* is `True`, put a `>` character in front of any line in the body that starts with the exact string `"From "`, that is `From` followed by a space at the beginning of a line. *mangle_from_* defaults to the value of the **`mangle_from_`** setting of the *policy* (which is `True` for the **`compat32`** policy and `False` for all others). *mangle_from_* is intended for use when messages are stored in Unix mbox format (see **`mailbox`** and WHY THE CONTENT-LENGTH FORMAT IS BAD [https://www.jwz.org/doc/content-length.html]).

If *maxheaderlen* is not `None`, refold any header lines that are longer than *maxheaderlen*, or if `0`, do not rewrap any headers. If *manheaderlen* is `None` (the default), wrap headers and other message lines according to the *policy* settings.

If *policy* is specified, use that policy to control message generation. If *policy* is `None` (the default), use the policy associated with the **`Message`** or **`EmailMessage`** object passed to `flatten` to control the message generation. See **`email.policy`** for details on what *policy* controls.

New in version 3.2.

Changed in version 3.3: Added the *policy* keyword.

Changed in version 3.6: The default behavior of the *mangle_from_* and *maxheaderlen* parameters is to follow the policy.

flatten(*msg*, *unixfrom*=*False*, *linesep*=*None*)

Print the textual representation of the message object structure rooted at *msg* to the output file specified when the **BytesGenerator** instance was created.

If the **policy** option **cte_type** is `8bit` (the default), copy any headers in the original parsed message that have not been modified to the output with any bytes with the high bit set reproduced as in the original, and preserve the non-ASCII *Content-Transfer-Encoding* of any body parts that have them. If `cte_type` is `7bit`, convert the bytes with the high bit set as needed using an ASCII-compatible *Content-Transfer-Encoding*. That is, transform parts with non-ASCII *Content-Transfer-Encoding* (*Content-Transfer-Encoding: 8bit*) to an ASCII compatible *Content-Transfer-Encoding*, and encode RFC-invalid non-ASCII bytes in headers using the MIME `unknown-8bit` character set, thus rendering them RFC-compliant.

If *unixfrom* is `True`, print the envelope header delimiter used by the Unix mailbox format (see **mailbox**) before the first of the **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] headers of the root message object. If the root object has no envelope header, craft a standard one. The default is `False`. Note that for subparts, no envelope header is ever printed.

If *linesep* is not `None`, use it as the separator character between all the lines of the flattened message. If *linesep* is `None` (the default), use the value specified in the *policy*.

clone(*fp*)

Return an independent clone of this **BytesGenerator** instance with the exact same option settings, and *fp* as the new *outfp*.

write(*s*)

Encode *s* using the `ASCII` codec and the `surrogateescape` error handler, and pass it to the *write* method of the *outfp* passed to the **`BytesGenerator`**'s constructor.

As a convenience, **`EmailMessage`** provides the methods **`as_bytes()`** and `bytes(aMessage)` (a.k.a. **`__bytes__()`**), which simplify the generation of a serialized binary representation of a message object. For more detail, see **`email.message`**.

Because strings cannot represent binary data, the **`Generator`** class must convert any binary data in any message it flattens to an ASCII compatible format, by converting them to an ASCII compatible *Content-Transfer_Encoding*. Using the terminology of the email RFCs, you can think of this as **`Generator`** serializing to an I/O stream that is not "8 bit clean". In other words, most applications will want to be using **`BytesGenerator`**, and not **`Generator`**.

class email.generator.Generator(*outfp*, *mangle_from_* = *None*, *maxheaderlen* = *None*, ***, *policy* = *None*)

Return a **`Generator`** object that will write any message provided to the **`flatten()`** method, or any text provided to the **`write()`** method, to the file-like object *outfp*. *outfp* must support a `write` method that accepts string data.

If optional *mangle_from_* is `True`, put a `>` character in front of any line in the body that starts with the exact string `"From "`, that is `From` followed by a space at the beginning of a line. *mangle_from_* defaults to the value of the **`mangle_from_`** setting of the *policy* (which is `True` for the **`compat32`** policy and `False` for all others). *mangle_from_* is intended for use when messages are stored in Unix mbox format (see **`mailbox`** and WHY THE CONTENT-LENGTH FORMAT IS BAD [https://www.jwz.org/doc/content-length.html]).

If *maxheaderlen* is not `None`, refold any header lines that are longer than *maxheaderlen*, or if `0`, do not rewrap any headers. If *manheaderlen* is `None` (the default), wrap headers and

other message lines according to the *policy* settings.

If *policy* is specified, use that policy to control message generation. If *policy* is `None` (the default), use the policy associated with the **`Message`** or **`EmailMessage`** object passed to `flatten` to control the message generation. See **`email.policy`** for details on what *policy* controls.

Changed in version 3.3: Added the *policy* keyword.

Changed in version 3.6: The default behavior of the *mangle_from_* and *maxheaderlen* parameters is to follow the policy.

flatten(*msg*, *unixfrom=False*, *linesep=None*)

Print the textual representation of the message object structure rooted at *msg* to the output file specified when the **`Generator`** instance was created.

If the **`policy`** option **`cte_type`** is `8bit`, generate the message as if the option were set to `7bit`. (This is required because strings cannot represent non-ASCII bytes.) Convert any bytes with the high bit set as needed using an ASCII-compatible *Content-Transfer-Encoding*. That is, transform parts with non-ASCII *Content-Transfer-Encoding* (*Content-Transfer-Encoding: 8bit*) to an ASCII compatible *Content-Transfer-Encoding*, and encode RFC-invalid non-ASCII bytes in headers using the MIME `unknown-8bit` character set, thus rendering them RFC-compliant.

If *unixfrom* is `True`, print the envelope header delimiter used by the Unix mailbox format (see **`mailbox`**) before the first of the **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] headers of the root message object. If the root object has no envelope header, craft a standard one. The default is `False`. Note that for subparts, no envelope header is ever printed.

If *linesep* is not `None`, use it as the separator character

between all the lines of the flattened message. If *linesep* is `None` (the default), use the value specified in the *policy*.

Changed in version 3.2: Added support for re-encoding `8bit` message bodies, and the *linesep* argument.

clone(*fp*)

Return an independent clone of this **`Generator`** instance with the exact same options, and *fp* as the new *outfp*.

write(*s*)

Write *s* to the *write* method of the *outfp* passed to the **`Generator`**'s constructor. This provides just enough file-like API for **`Generator`** instances to be used in the **`print()`** function.

As a convenience, **`EmailMessage`** provides the methods **`as_string()`** and `str(aMessage)` (a.k.a. **`__str__()`**), which simplify the generation of a formatted string representation of a message object. For more detail, see **`email.message`**.

The **`email.generator`** module also provides a derived class, **`DecodedGenerator`**, which is like the **`Generator`** base class, except that non-*text* parts are not serialized, but are instead represented in the output stream by a string derived from a template filled in with information about the part.

class email.generator.DecodedGenerator(*outfp*, *mangle_from_*=*None*, *maxheaderlen*=*None*, *fmt*=*None*, ***, *policy*=*None*)

Act like **`Generator`**, except that for any subpart of the message passed to **`Generator.flatten()`**, if the subpart is of main type *text*, print the decoded payload of the subpart, and if the main type is not *text*, instead of printing it fill in the string *fmt* using information from the part and print the resulting filled-in string.

To fill in *fmt*, execute `fmt % part_info`, where

`part_info` is a dictionary composed of the following keys and values:

- `type` – Full MIME type of the non-*text* part
- `maintype` – Main MIME type of the non-*text* part
- `subtype` – Sub-MIME type of the non-*text* part
- `filename` – Filename of the non-*text* part
- `description` – Description associated with the non-*text* part
- `encoding` – Content transfer encoding of the non-*text* part

If *fmt* is `None`, use the following default *fmt*:

> "[Non-text (%(type)s) part of message omitted, filename %(filename)s]"

Optional *_mangle_from_* and *maxheaderlen* are as with the **`Generator`** base class.

Footnotes

1

This statement assumes that you use the appropriate setting for `unixfrom`, and that there are no **`policy`** settings calling for automatic adjustments (for example, **`refold_source`** must be `none`, which is *not* the default). It is also not 100% true, since if the message does not conform to the RFC standards occasionally information about the exact original text is lost during parsing error recovery. It is a goal to fix these latter edge cases when possible.

`email.policy`: Policy Objects

New in version 3.3.

Source code: Lib/email/policy.py [https://github.com/python/cpython/tree/3.11/Lib/email/policy.py]

The `email` package's prime focus is the handling of email messages as described by the various email and MIME RFCs. However, the general format of email messages (a block of header fields each consisting of a name followed by a colon followed by a value, the whole block followed by a blank line and an arbitrary 'body'), is a format that has found utility outside of the realm of email. Some of these uses conform fairly closely to the main email RFCs, some do not. Even when working with email, there are times when it is desirable to break strict compliance with the RFCs, such as generating emails that interoperate with email servers that do not themselves follow the standards, or that implement extensions you want to use in ways that violate the standards.

Policy objects give the email package the flexibility to handle all these disparate use cases.

A `Policy` object encapsulates a set of attributes and methods that control the behavior of various components of the email package during use. `Policy` instances can be passed to various classes and methods in the email package to alter the default behavior. The settable values and their defaults are described below.

There is a default policy used by all classes in the email package. For all of the `parser` classes and the related convenience functions, and for the `Message` class, this is the `Compat32` policy, via its corresponding pre-defined instance `compat32`. This policy provides for complete backward compatibility (in some cases, including bug compatibility) with the pre-Python3.3 version of the email package.

This default value for the *policy* keyword to **EmailMessage** is the **EmailPolicy** policy, via its pre-defined instance **default**.

When a **Message** or **EmailMessage** object is created, it acquires a policy. If the message is created by a **parser**, a policy passed to the parser will be the policy used by the message it creates. If the message is created by the program, then the policy can be specified when it is created. When a message is passed to a **generator**, the generator uses the policy from the message by default, but you can also pass a specific policy to the generator that will override the one stored on the message object.

The default value for the *policy* keyword for the **email.parser** classes and the parser convenience functions **will be changing** in a future version of Python. Therefore you should **always specify explicitly which policy you want to use** when calling any of the classes and functions described in the **parser** module.

The first part of this documentation covers the features of **Policy**, an abstract base class that defines the features that are common to all policy objects, including **compat32**. This includes certain hook methods that are called internally by the email package, which a custom policy could override to obtain different behavior. The second part describes the concrete classes **EmailPolicy** and **Compat32**, which implement the hooks that provide the standard behavior and the backward compatible behavior and features, respectively.

Policy instances are immutable, but they can be cloned, accepting the same keyword arguments as the class constructor and returning a new **Policy** instance that is a copy of the original but with the specified attributes values changed.

As an example, the following code could be used to read an email message from a file on disk and pass it to the system `sendmail` program on a Unix system:

```
>>> from email import message_from_binary_file
>>> from email.generator import BytesGenerator
>>> from email import policy
>>> from subprocess import Popen, PIPE
```

```
>>> with open('mymsg.txt', 'rb') as f:
...     msg = message_from_binary_file(f, policy=policy.
>>> p = Popen(['sendmail', msg['To'].addresses[0]], stdi
>>> g = BytesGenerator(p.stdin, policy=msg.policy.clone(
>>> g.flatten(msg)
>>> p.stdin.close()
>>> rc = p.wait()
```

Here we are telling **`BytesGenerator`** to use the RFC correct line separator characters when creating the binary string to feed into `sendmail's stdin`, where the default policy would use `\n` line separators.

Some email package methods accept a *policy* keyword argument, allowing the policy to be overridden for that method. For example, the following code uses the **`as_bytes()`** method of the *msg* object from the previous example and writes the message to a file using the native line separators for the platform on which it is running:

```
>>> import os
>>> with open('converted.txt', 'wb') as f:
...     f.write(msg.as_bytes(policy=msg.policy.clone(lin
17
```

Policy objects can also be combined using the addition operator, producing a policy object whose settings are a combination of the non-default values of the summed objects:

```
>>> compat_SMTP = policy.compat32.clone(linesep='\r\n')
>>> compat_strict = policy.compat32.clone(raise_on_defec
>>> compat_strict_SMTP = compat_SMTP + compat_strict
```

This operation is not commutative; that is, the order in which the objects are added matters. To illustrate:

```
>>> policy100 = policy.compat32.clone(max_line_length=10
>>> policy80 = policy.compat32.clone(max_line_length=80)
>>> apolicy = policy100 + policy80
>>> apolicy.max_line_length
80
```

```
>>> apolicy = policy80 + policy100
>>> apolicy.max_line_length
100
```

class email.policy.Policy(***kw*)

This is the abstract base class for all policy classes. It provides default implementations for a couple of trivial methods, as well as the implementation of the immutability property, the **`clone()`** method, and the constructor semantics.

The constructor of a policy class can be passed various keyword arguments. The arguments that may be specified are any non-method properties on this class, plus any additional non-method properties on the concrete class. A value specified in the constructor will override the default value for the corresponding attribute.

This class defines the following properties, and thus values for the following may be passed in the constructor of any policy class:

max_line_length

The maximum length of any line in the serialized output, not counting the end of line character(s). Default is 78, per **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html]. A value of `0` or **`None`** indicates that no line wrapping should be done at all.

linesep

The string to be used to terminate lines in serialized output. The default is `\n` because that's the internal end-of-line discipline used by Python, though `\r\n` is required by the RFCs.

cte_type

Controls the type of Content Transfer Encodings that may be or are required to be used. The possible values are:

7bit all data must be “7 bit clean” (ASCII-only). This means that where necessary data will be encoded using either quoted-printable or base64 encoding.

8bit data is not constrained to be 7 bit clean. Data in headers is still required to be ASCII-only and so will be encoded (see **`fold_binary()`** and **`utf8`** below for exceptions), but body parts may use the `8bit` CTE.

A `cte_type` value of `8bit` only works with `BytesGenerator`, not `Generator`, because strings cannot contain binary data. If a `Generator` is operating under a policy that specifies `cte_type=8bit`, it will act as if `cte_type` is `7bit`.

raise_on_defect

If **`True`**, any defects encountered will be raised as errors. If **`False`** (the default), defects will be passed to the **`register_defect()`** method.

mangle_from_

If **`True`**, lines starting with *“From “* in the body are escaped by putting a `>` in front of them. This parameter is used when the message is being serialized by a generator. Default: **`False`**.

New in version 3.5: The *mangle_from_* parameter.

message_factory

A factory function for constructing a new empty message object. Used by the parser when building messages. Defaults to `None`, in which case **`Message`** is used.

New in version 3.6.

The following **`Policy`** method is intended to be called by code using the email library to create policy instances with custom settings:

clone(***kw*)

Return a new **`Policy`** instance whose attributes have the same values as the current instance, except where those attributes are given new values by the keyword arguments.

The remaining **`Policy`** methods are called by the email package code, and are not intended to be called by an application using the email package. A custom policy must implement all of these methods.

handle_defect(*obj*, *defect*)

Handle a *defect* found on *obj*. When the email package calls this method, *defect* will always be a subclass of **`Defect`**.

The default implementation checks the **`raise_on_defect`** flag. If it is `True`, *defect* is raised as an exception. If it is `False` (the default), *obj* and *defect* are passed to **`register_defect()`**.

register_defect(*obj*, *defect*)

Register a *defect* on *obj*. In the email package, *defect* will always be a subclass of **`Defect`**.

The default implementation calls the `append` method of the `defects` attribute of *obj*. When the email package calls **`handle_defect`**, *obj* will normally have a `defects` attribute that has an `append` method. Custom object types used with the email package (for example, custom `Message` objects) should also provide such an attribute, otherwise defects in parsed messages will raise unexpected errors.

header_max_count(*name*)

Return the maximum allowed number of headers named *name*.

Called when a header is added to an **`EmailMessage`**

or **Message** object. If the returned value is not `0` or `None`, and there are already a number of headers with the name *name* greater than or equal to the value returned, a **ValueError** is raised.

Because the default behavior of `Message.__setitem__` is to append the value to the list of headers, it is easy to create duplicate headers without realizing it. This method allows certain headers to be limited in the number of instances of that header that may be added to a `Message` programmatically. (The limit is not observed by the parser, which will faithfully produce as many headers as exist in the message being parsed.)

The default implementation returns `None` for all header names.

header_source_parse(*sourcelines*)

The email package calls this method with a list of strings, each string ending with the line separation characters found in the source being parsed. The first line includes the field header name and separator. All whitespace in the source is preserved. The method should return the `(name, value)` tuple that is to be stored in the `Message` to represent the parsed header.

If an implementation wishes to retain compatibility with the existing email package policies, *name* should be the case preserved name (all characters up to the ‘`:`’ separator), while *value* should be the unfolded value (all line separator characters removed, but whitespace kept intact), stripped of leading whitespace.

sourcelines may contain surrogateescaped binary data.

There is no default implementation

header_store_parse(*name*, *value*)

The email package calls this method with the name and

value provided by the application program when the application program is modifying a `Message` programmatically (as opposed to a `Message` created by a parser). The method should return the `(name, value)` tuple that is to be stored in the `Message` to represent the header.

If an implementation wishes to retain compatibility with the existing email package policies, the *name* and *value* should be strings or string subclasses that do not change the content of the passed in arguments.

There is no default implementation

header_fetch_parse(*name*, *value*)

The email package calls this method with the *name* and *value* currently stored in the `Message` when that header is requested by the application program, and whatever the method returns is what is passed back to the application as the value of the header being retrieved. Note that there may be more than one header with the same name stored in the `Message`; the method is passed the specific name and value of the header destined to be returned to the application.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the value returned by the method.

There is no default implementation

fold(*name*, *value*)

The email package calls this method with the *name* and *value* currently stored in the `Message` for a given header. The method should return a string that represents that header "folded" correctly (according to the policy settings) by composing the *name* with the *value* and inserting **`linesep`** characters at the appropriate places. See **RFC 5322** [https://

datatracker.ietf.org/doc/html/rfc5322.html] for a discussion of the rules for folding email headers.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the string returned by the method.

fold_binary(*name*, *value*)

The same as **`fold()`**, except that the returned value should be a bytes object rather than a string.

value may contain surrogateescaped binary data. These could be converted back into binary data in the returned bytes object.

class email.policy.EmailPolicy(***kw*)

This concrete **`Policy`** provides behavior that is intended to be fully compliant with the current email RFCs. These include (but are not limited to) **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html], **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html], and the current MIME RFCs.

This policy adds new header parsing and folding algorithms. Instead of simple strings, headers are `str` subclasses with attributes that depend on the type of the field. The parsing and folding algorithm fully implement **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html] and **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html].

The default value for the **`message_factory`** attribute is **`EmailMessage`**.

In addition to the settable attributes listed above that apply to all policies, this policy adds the following additional attributes:

New in version 3.6: 1

utf8

If `False`, follow **RFC 5322** [https://datatracker.ietf.org/doc/

html/rfc5322.html], supporting non-ASCII characters in headers by encoding them as “encoded words”. If `True`, follow **RFC 6532** [https://datatracker.ietf.org/doc/html/rfc6532.html] and use `utf-8` encoding for headers. Messages formatted in this way may be passed to SMTP servers that support the `SMTPUTF8` extension (**RFC 6531** [https://datatracker.ietf.org/doc/html/rfc6531.html]).

refold_source

If the value for a header in the `Message` object originated from a **`parser`** (as opposed to being set by a program), this attribute indicates whether or not a generator should refold that value when transforming the message back into serialized form. The possible values are:

`none`	all source values use original folding
`long`	source values that have any line that is longer than `max_line_length` will be refolded
`all`	all values are refolded.

The default is `long`.

header_factory

A callable that takes two arguments, `name` and `value`, where `name` is a header field name and `value` is an unfolded header field value, and returns a string subclass that represents that header. A default `header_factory` (see **`headerregistry`**) is provided that supports custom parsing for the various address and date **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] header field types, and the major MIME header field stypes. Support for additional custom parsing will be added in the future.

content_manager

An object with at least two methods: get_content and set_content. When the **`get_content()`** or **`set_content()`** method of an **`EmailMessage`** object

is called, it calls the corresponding method of this object, passing it the message object as its first argument, and any arguments or keywords that were passed to it as additional arguments. By default `content_manager` is set to **`raw_data_manager`**.

New in version 3.4.

The class provides the following concrete implementations of the abstract methods of **`Policy`**:

header_max_count(*name*)

Returns the value of the **`max_count`** attribute of the specialized class used to represent the header with the given name.

header_source_parse(*sourcelines*)

The name is parsed as everything up to the '`:`' and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

header_store_parse(*name*, *value*)

The name is returned unchanged. If the input value has a `name` attribute and it matches *name* ignoring case, the value is returned unchanged. Otherwise the *name* and *value* are passed to `header_factory`, and the resulting header object is returned as the value. In this case a `ValueError` is raised if the input value contains CR or LF characters.

header_fetch_parse(*name*, *value*)

If the value has a `name` attribute, it is returned to unmodified. Otherwise the *name*, and the *value* with any CR or LF characters removed, are passed to the `header_factory`, and the resulting header object is

returned. Any surrogateescaped bytes get turned into the unicode unknown-character glyph.

fold(*name*, *value*)

Header folding is controlled by the **refold_source** policy setting. A value is considered to be a 'source value' if and only if it does not have a `name` attribute (having a `name` attribute means it is a header object of some sort). If a source value needs to be refolded according to the policy, it is converted into a header object by passing the *name* and the *value* with any CR and LF characters removed to the `header_factory`. Folding of a header object is done by calling its `fold` method with the current policy.

Source values are split into lines using **splitlines()**. If the value is not to be refolded, the lines are rejoined using the `linesep` from the policy and returned. The exception is lines containing non-ascii binary data. In that case the value is refolded regardless of the `refold_source` setting, which causes the binary data to be CTE encoded using the `unknown-8bit` charset.

fold_binary(*name*, *value*)

The same as **fold()** if **cte_type** is `7bit`, except that the returned value is bytes.

If **cte_type** is `8bit`, non-ASCII binary data is converted back into bytes. Headers with binary data are not refolded, regardless of the `refold_header` setting, since there is no way to know whether the binary data consists of single byte characters or multibyte characters.

The following instances of **EmailPolicy** provide defaults suitable for specific application domains. Note that in the future the behavior of these instances (in particular the `HTTP` instance) may be adjusted to conform even more closely to the RFCs relevant to

their domains.

email.policy.default

An instance of `EmailPolicy` with all defaults unchanged. This policy uses the standard Python `\n` line endings rather than the RFC-correct `\r\n`.

email.policy.SMTP

Suitable for serializing messages in conformance with the email RFCs. Like `default`, but with `linesep` set to `\r\n`, which is RFC compliant.

email.policy.SMTPUTF8

The same as `SMTP` except that **`utf8`** is `True`. Useful for serializing messages to a message store without using encoded words in the headers. Should only be used for SMTP transmission if the sender or recipient addresses have non-ASCII characters (the **`smtplib.SMTP.send_message()`** method handles this automatically).

email.policy.HTTP

Suitable for serializing headers with for use in HTTP traffic. Like `SMTP` except that `max_line_length` is set to `None` (unlimited).

email.policy.strict

Convenience instance. The same as `default` except that `raise_on_defect` is set to `True`. This allows any policy to be made strict by writing:

```
somepolicy + policy.strict
```

With all of these **`EmailPolicies`**, the effective API of the email package is changed from the Python 3.2 API in the following ways:

- Setting a header on a **`Message`** results in that header being parsed and a header object created.
- Fetching a header value from a **`Message`**

results in that header being parsed and a header object created and returned.
- Any header object, or any header that is refolded due to the policy settings, is folded using an algorithm that fully implements the RFC folding algorithms, including knowing where encoded words are required and allowed.

From the application view, this means that any header obtained through the **EmailMessage** is a header object with extra attributes, whose string value is the fully decoded unicode value of the header. Likewise, a header may be assigned a new value, or a new header created, using a unicode string, and the policy will take care of converting the unicode string into the correct RFC encoded form.

The header objects and their attributes are described in **headerregistry**.

class email.policy.Compat32(***kw*)

This concrete **Policy** is the backward compatibility policy. It replicates the behavior of the email package in Python 3.2. The **policy** module also defines an instance of this class, **compat32**, that is used as the default policy. Thus the default behavior of the email package is to maintain compatibility with Python 3.2.

The following attributes have values that are different from the **Policy** default:

mangle_from_

The default is `True`.

The class provides the following concrete implementations of the abstract methods of **Policy**:

header_source_parse(*sourcelines*)

The name is parsed as everything up to the '`:`' and returned unmodified. The value is determined by

stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

header_store_parse(*name*, *value*)

The name and value are returned unmodified.

header_fetch_parse(*name*, *value*)

If the value contains binary data, it is converted into a **Header** object using the `unknown-8bit` charset. Otherwise it is returned unmodified.

fold(*name*, *value*)

Headers are folded using the **Header** folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the `max_line_length`. Non-ASCII binary data are CTE encoded using the `unknown-8bit` charset.

fold_binary(*name*, *value*)

Headers are folded using the **Header** folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the `max_line_length`. If `cte_type` is `7bit`, non-ascii binary data is CTE encoded using the `unknown-8bit` charset. Otherwise the original source header is used, with its existing line breaks and any (RFC invalid) binary data it may contain.

email.policy.compat32

An instance of **Compat32**, providing backward compatibility with the behavior of the email package in Python 3.2.

Footnotes

[1] Originally added in 3.3 as a provisional feature.

`email.errors`: Exception and Defect classes

Source code: Lib/email/errors.py [https://github.com/python/cpython/tree/3.11/Lib/email/errors.py]

The following exception classes are defined in the `email.errors` module:

exception email.errors.MessageError

This is the base class for all exceptions that the `email` package can raise. It is derived from the standard `Exception` class and defines no additional methods.

exception email.errors.MessageParseError

This is the base class for exceptions raised by the `Parser` class. It is derived from `MessageError`. This class is also used internally by the parser used by `headerregistry`.

exception email.errors.HeaderParseError

Raised under some error conditions when parsing the RFC 5322 [https://datatracker.ietf.org/doc/html/rfc5322.html] headers of a message, this class is derived from `MessageParseError`. The `set_boundary()` method will raise this error if the content type is unknown when the method is called. `Header` may raise this error for certain base64 decoding errors, and when an attempt is made to create a header that appears to contain an embedded header (that is, there is what is supposed to be a continuation line that has no leading whitespace and looks like a header).

exception email.errors.BoundaryError

Deprecated and no longer used.

exception email.errors.MultipartConversionError

Raised when a payload is added to a **Message** object using **add_payload()**, but the payload is already a scalar and the message's *Content-Type* main type is not either *multipart* or missing. **MultipartConversionError** multiply inherits from **MessageError** and the built-in **TypeError**.

Since **Message.add_payload()** is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the **attach()** method is called on an instance of a class derived from **MIMENonMultipart** (e.g. **MIMEImage**).

Here is the list of the defects that the **FeedParser** can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a *multipart/alternative* had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from **email.errors.MessageDefect**.

- **NoBoundaryInMultipartDefect** – A message claimed to be a multipart, but had no *boundary* parameter.
- **StartBoundaryNotFoundDefect** – The start boundary claimed in the *Content-Type* header was never found.
- **CloseBoundaryNotFoundDefect** – A start boundary was found, but no corresponding close boundary was ever found.

  New in version 3.3.
- **FirstHeaderLineIsContinuationDefect** – The message had a continuation line as its first header line.
- **MisplacedEnvelopeHeaderDefect** - A "Unix From" header was found in the middle of a header block.
- **MissingHeaderBodySeparatorDefect** - A line was found

while parsing headers that had no leading white space but contained no ':'. Parsing continues assuming that the line represents the first line of the body.

New in version 3.3.

- **MalformedHeaderDefect** – A header was found that was missing a colon, or was otherwise malformed.

  Deprecated since version 3.3: This defect has not been used for several Python versions.

- **MultipartInvariantViolationDefect** – A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its `is_multipart()` method may return `False` even though its content type claims to be *multipart*.

- **InvalidBase64PaddingDefect** – When decoding a block of base64 encoded bytes, the padding was not correct. Enough padding is added to perform the decode, but the resulting decoded bytes may be invalid.

- **InvalidBase64CharactersDefect** – When decoding a block of base64 encoded bytes, characters outside the base64 alphabet were encountered. The characters are ignored, but the resulting decoded bytes may be invalid.

- **InvalidBase64LengthDefect** – When decoding a block of base64 encoded bytes, the number of non-padding base64 characters was invalid (1 more than a multiple of 4). The encoded block was kept as-is.

- **InvalidDateDefect** – When decoding an invalid or unparsable date field. The original value is kept as-is.

email.headerregistry: Custom Header Objects

Source code: Lib/email/headerregistry.py [https://github.com/python/cpython/tree/3.11/Lib/email/headerregistry.py]

New in version 3.6: 1

Headers are represented by customized subclasses of `str`. The particular class used to represent a given header is determined by the `header_factory` of the `policy` in effect when the headers are created. This section documents the particular `header_factory` implemented by the email package for handling **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] compliant email messages, which not only provides customized header objects for various header types, but also provides an extension mechanism for applications to add their own custom header types.

When using any of the policy objects derived from `EmailPolicy`, all headers are produced by `HeaderRegistry` and have `BaseHeader` as their last base class. Each header class has an additional base class that is determined by the type of the header. For example, many headers have the class `UnstructuredHeader` as their other base class. The specialized second class for a header is determined by the name of the header, using a lookup table stored in the `HeaderRegistry`. All of this is managed transparently for the typical application program, but interfaces are provided for modifying the default behavior for use by more complex applications.

The sections below first document the header base classes and their attributes, followed by the API for modifying the behavior of `HeaderRegistry`, and finally the support classes used to represent the data parsed from structured headers.

class email.headerregistry.BaseHeader(*name*, *value*)

name and *value* are passed to `BaseHeader` from the **`header_factory`** call. The string value of any header object is the *value* fully decoded to unicode.

This base class defines the following read-only properties:

name

The name of the header (the portion of the field before the ':'). This is exactly the value passed in the **`header_factory`** call for *name*; that is, case is preserved.

defects

A tuple of **`HeaderDefect`** instances reporting any RFC compliance problems found during parsing. The email package tries to be complete about detecting compliance issues. See the **`errors`** module for a discussion of the types of defects that may be reported.

max_count

The maximum number of headers of this type that can have the same `name`. A value of `None` means unlimited. The `BaseHeader` value for this attribute is `None`; it is expected that specialized header classes will override this value as needed.

`BaseHeader` also provides the following method, which is called by the email library code and should not in general be called by application programs:

fold(*, *policy*)

Return a string containing **`linesep`** characters as required to correctly fold the header according to *policy*. A **`cte_type`** of `8bit` will be treated as if it were `7bit`, since headers may not contain arbitrary binary data. If **`utf8`** is `False`, non-ASCII data will be **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html] encoded.

`BaseHeader` by itself cannot be used to create a header object. It defines a protocol that each specialized header cooperates with in order to produce the header object. Specifically, `BaseHeader` requires that the specialized class provide a **`classmethod()`** named `parse`. This method is called as follows:

```
parse(string, kwds)
```

`kwds` is a dictionary containing one pre-initialized key, `defects`. `defects` is an empty list. The parse method should append any detected defects to this list. On return, the `kwds` dictionary *must* contain values for at least the keys `decoded` and `defects`. `decoded` should be the string value for the header (that is, the header value fully decoded to unicode). The parse method should assume that *string* may contain content-transfer-encoded parts, but should correctly handle all valid unicode characters as well so that it can parse un-encoded header values.

`BaseHeader`'s `__new__` then creates the header instance, and calls its `init` method. The specialized class only needs to provide an `init` method if it wishes to set additional attributes beyond those provided by `BaseHeader` itself. Such an `init` method should look like this:

```
def init(self, /, *args, **kw):
    self._myattr = kw.pop('myattr')
    super().init(*args, **kw)
```

That is, anything extra that the specialized class puts in to the `kwds` dictionary should be removed and handled, and the remaining contents of `kw` (and `args`) passed to the `BaseHeader init` method.

class email.headerregistry.UnstructuredHeader

An "unstructured" header is the default type of header in **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html]. Any header that does not have a specified syntax is treated as unstructured. The classic example of an unstructured header

is the *Subject* header.

In **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html], an unstructured header is a run of arbitrary text in the ASCII character set. **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html], however, has an **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] compatible mechanism for encoding non-ASCII text as ASCII characters within a header value. When a *value* containing encoded words is passed to the constructor, the `UnstructuredHeader` parser converts such encoded words into unicode, following the **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html] rules for unstructured text. The parser uses heuristics to attempt to decode certain non-compliant encoded words. Defects are registered in such cases, as well as defects for issues such as invalid characters within the encoded words or the non-encoded text.

This header type provides no additional attributes.

class email.headerregistry.DateHeader

RFC 5322 [https://datatracker.ietf.org/doc/html/rfc5322.html] specifies a very specific format for dates within email headers. The `DateHeader` parser recognizes that date format, as well as recognizing a number of variant forms that are sometimes found "in the wild".

This header type provides the following additional attributes:

datetime

If the header value can be recognized as a valid date of one form or another, this attribute will contain a **`datetime`** instance representing that date. If the timezone of the input date is specified as `-0000` (indicating it is in UTC but contains no information about the source timezone), then **`datetime`** will be a naive **`datetime`**. If a specific timezone offset is found (including `+0000`), then **`datetime`** will contain an aware `datetime` that uses **`datetime.timezone`** to record the timezone offset.

The `decoded` value of the header is determined by formatting the `datetime` according to the **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] rules; that is, it is set to:

```
email.utils.format_datetime(self.datetime)
```

When creating a `DateHeader`, *value* may be **`datetime`** instance. This means, for example, that the following code is valid and does what one would expect:

```
msg['Date'] = datetime(2011, 7, 15, 21)
```

Because this is a naive `datetime` it will be interpreted as a UTC timestamp, and the resulting value will have a timezone of `-0000`. Much more useful is to use the **`localtime()`** function from the **`utils`** module:

```
msg['Date'] = utils.localtime()
```

This example sets the date header to the current time and date using the current timezone offset.

class email.headerregistry.AddressHeader

Address headers are one of the most complex structured header types. The `AddressHeader` class provides a generic interface to any address header.

This header type provides the following additional attributes:

groups

A tuple of **`Group`** objects encoding the addresses and groups found in the header value. Addresses that are not part of a group are represented in this list as single-address `Groups` whose **`display_name`** is `None`.

addresses

A tuple of **`Address`** objects encoding all of the individual addresses from the header value. If the header value contains any groups, the individual addresses from the group are included in the list at the

point where the group occurs in the value (that is, the list of addresses is "flattened" into a one dimensional list).

The `decoded` value of the header will have all encoded words decoded to unicode. **`idna`** encoded domain names are also decoded to unicode. The `decoded` value is set by joining the **`str`** value of the elements of the `groups` attribute with `', '`.

A list of **`Address`** and **`Group`** objects in any combination may be used to set the value of an address header. `Group` objects whose `display_name` is `None` will be interpreted as single addresses, which allows an address list to be copied with groups intact by using the list obtained from the `groups` attribute of the source header.

class email.headerregistry.SingleAddressHeader

A subclass of **`AddressHeader`** that adds one additional attribute:

address

The single address encoded by the header value. If the header value actually contains more than one address (which would be a violation of the RFC under the default **`policy`**), accessing this attribute will result in a **`ValueError`**.

Many of the above classes also have a `Unique` variant (for example, `UniqueUnstructuredHeader`). The only difference is that in the `Unique` variant, **`max_count`** is set to 1.

class email.headerregistry.MIMEVersionHeader

There is really only one valid value for the *MIME-Version* header, and that is `1.0`. For future proofing, this header class supports other valid version numbers. If a version number has a valid value per **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html], then the header object will have non-`None` values for the following attributes:

version

The version number as a string, with any whitespace and/or comments removed.

major

The major version number as an integer

minor

The minor version number as an integer

class email.headerregistry.ParameterizedMIMEHeader

MIME headers all start with the prefix 'Content-'. Each specific header has a certain value, described under the class for that header. Some can also take a list of supplemental parameters, which have a common format. This class serves as a base for all the MIME headers that take parameters.

params

A dictionary mapping parameter names to parameter values.

class email.headerregistry.ContentTypeHeader

A **`ParameterizedMIMEHeader`** class that handles the *Content-Type* header.

content_type

The content type string, in the form `maintype/subtype`.

maintype

subtype

class email.headerregistry.ContentDispositionHeader

A **`ParameterizedMIMEHeader`** class that handles the *Content-Disposition* header.

content_disposition

`inline` and `attachment` are the only valid values in common use.

class email.headerregistry.ContentTransferEncoding

Handles the *Content-Transfer-Encoding* header.

cte

Valid values are `7bit`, `8bit`, `base64`, and `quoted-printable`. See **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html] for more information.

class email.headerregistry.HeaderRegistry(*base_class* = *BaseHeader*, *default_class* = *UnstructuredHeader*, *use_default_map* = *True*)

This is the factory used by **`EmailPolicy`** by default. `HeaderRegistry` builds the class used to create a header instance dynamically, using *base_class* and a specialized class retrieved from a registry that it holds. When a given header name does not appear in the registry, the class specified by *default_class* is used as the specialized class. When *use_default_map* is `True` (the default), the standard mapping of header names to classes is copied in to the registry during initialization. *base_class* is always the last class in the generated class's `__bases__` list.

The default mappings are:

subject
: UniqueUnstructuredHeader

date
: UniqueDateHeader

resent-date
: DateHeader

orig-date
: UniqueDateHeader

MessageIDHeader

`HeaderRegistry` has the following methods:

map_to_type(*self*, *name*, *cls*)

name is the name of the header to be mapped. It will be converted to lower case in the registry. *cls* is the specialized class to be used, along with *base_class*, to create the class used to instantiate headers that match *name*.

getitem(*name*)

Construct and return a class to handle creating a *name*

header.

call(*name*, *value*)

Retrieves the specialized header associated with *name* from the registry (using *default_class* if *name* does not appear in the registry) and composes it with *base_class* to produce a class, calls the constructed class's constructor, passing it the same argument list, and finally returns the class instance created thereby.

The following classes are the classes used to represent data parsed from structured headers and can, in general, be used by an application program to construct structured values to assign to specific headers.

class email.headerregistry.Address(*display_name*=*''*, *username*=*''*, *domain*=*''*, *addr_spec*=*None*)

The class used to represent an email address. The general form of an address is:

```
[display_name] <username@domain>
```

or:

```
username@domain
```

where each part must conform to specific syntax rules spelled out in **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html].

As a convenience *addr_spec* can be specified instead of *username* and *domain*, in which case *username* and *domain* will be parsed from the *addr_spec*. An *addr_spec* must be a properly RFC quoted string; if it is not `Address` will raise an error. Unicode characters are allowed and will be property encoded when serialized. However, per the RFCs, unicode is *not* allowed in the username portion of the address.

display_name

The display name portion of the address, if any, with all

quoting removed. If the address does not have a display name, this attribute will be an empty string.

username

The `username` portion of the address, with all quoting removed.

domain

The `domain` portion of the address.

addr_spec

The `username@domain` portion of the address, correctly quoted for use as a bare address (the second form shown above). This attribute is not mutable.

str()

The `str` value of the object is the address quoted according to **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] rules, but with no Content Transfer Encoding of any non-ASCII characters.

To support SMTP (**RFC 5321** [https://datatracker.ietf.org/doc/html/rfc5321.html]), `Address` handles one special case: if `username` and `domain` are both the empty string (or `None`), then the string value of the `Address` is `<>`.

class email.headerregistry.Group(*display_name=None*, *addresses=None*)

The class used to represent an address group. The general form of an address group is:

```
display_name: [address-list];
```

As a convenience for processing lists of addresses that consist of a mixture of groups and single addresses, a `Group` may also be used to represent single addresses that are not part of a group by setting *display_name* to `None` and providing a list of the single address as *addresses*.

display_name

The `display_name` of the group. If it is `None` and there is exactly one `Address` in `addresses`, then the `Group` represents a single address that is not in a group.

addresses

A possibly empty tuple of **`Address`** objects representing the addresses in the group.

str()

The `str` value of a `Group` is formatted according to **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html], but with no Content Transfer Encoding of any non-ASCII characters. If `display_name` is none and there is a single `Address` in the `addresses` list, the `str` value will be the same as the `str` of that single `Address`.

Originally added in 3.3 as a provisional module

email.contentmanager: Managing MIME Content

Source code: Lib/email/contentmanager.py [https://github.com/python/cpython/tree/3.11/Lib/email/contentmanager.py]

New in version 3.6: 1

class email.contentmanager.ContentManager

Base class for content managers. Provides the standard registry mechanisms to register converters between MIME content and other representations, as well as the `get_content` and `set_content` dispatch methods.

get_content(*msg*, **args*, ***kw*)

Look up a handler function based on the `mimetype` of *msg* (see next paragraph), call it, passing through all arguments, and return the result of the call. The expectation is that the handler will extract the payload from *msg* and return an object that encodes information about the extracted data.

To find the handler, look for the following keys in the registry, stopping with the first one found:

- the string representing the full MIME type (`maintype/subtype`)
- the string representing the `maintype`
- the empty string

If none of these keys produce a handler, raise a **KeyError** for the full MIME type.

set_content(*msg*, *obj*, **args*, ***kw*)

If the `maintype` is `multipart`, raise a **`TypeError`**; otherwise look up a handler function based on the type of *obj* (see next paragraph), call **`clear_content()`** on the *msg*, and call the handler function, passing through all arguments. The expectation is that the handler will transform and store *obj* into *msg*, possibly making other changes to *msg* as well, such as adding various MIME headers to encode information needed to interpret the stored data.

To find the handler, obtain the type of *obj* (`typ = type(obj)`), and look for the following keys in the registry, stopping with the first one found:

- the type itself (`typ`)
- the type's fully qualified name (`typ.__module__ + '.' + typ.__qualname__`).
- the type's qualname (`typ.__qualname__`)
- the type's name (`typ.__name__`).

If none of the above match, repeat all of the checks above for each of the types in the MRO (`typ.__mro__`). Finally, if no other key yields a handler, check for a handler for the key `None`. If there is no handler for `None`, raise a **`KeyError`** for the fully qualified name of the type.

Also add a *MIME-Version* header if one is not present (see also **`MIMEPart`**).

add_get_handler(*key*, *handler*)

Record the function *handler* as the handler for *key*. For the possible values of *key*, see **`get_content()`**.

add_set_handler(*typekey*, *handler*)

Record *handler* as the function to call when an object of a type matching *typekey* is passed to **set_content()**. For the possible values of *typekey*, see **set_content()**.

Content Manager Instances

Currently the email package provides only one concrete content manager, **raw_data_manager**, although more may be added in the future. **raw_data_manager** is the **content_manager** provided by **EmailPolicy** and its derivatives.

email.contentmanager.raw_data_manager

This content manager provides only a minimum interface beyond that provided by **Message** itself: it deals only with text, raw byte strings, and **Message** objects. Nevertheless, it provides significant advantages compared to the base API: `get_content` on a text part will return a unicode string without the application needing to manually decode it, `set_content` provides a rich set of options for controlling the headers added to a part and controlling the content transfer encoding, and it enables the use of the various `add_` methods, thereby simplifying the creation of multipart messages.

email.contentmanager.get_content(*msg*, *errors='replace'*)

Return the payload of the part as either a string (for `text` parts), an **EmailMessage** object (for `message/rfc822` parts), or a `bytes` object (for all other non-multipart types). Raise a **KeyError** if called on a `multipart`. If the part is a `text` part and *errors* is specified, use it as the error handler when decoding the payload to unicode. The default error handler is `replace`.

email.contentmanager.set_content(*msg*, *<'str'>*, *subtype="plain"*, *charset='utf-8'*, *cte=None*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)

email.contentmanager.set_content(*msg*, *<'bytes'>*, *maintype*, *subtype*, *cte="base64"*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)
email.contentmanager.set_content(*msg*, *<'EmailMessage'>*, *cte=None*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)

Add headers and payload to *msg*:

Add a *Content-Type* header with a `maintype/subtype` value.

- For `str`, set the MIME `maintype` to `text`, and set the subtype to *subtype* if it is specified, or `plain` if it is not.
- For `bytes`, use the specified *maintype* and *subtype*, or raise a **`TypeError`** if they are not specified.
- For **`EmailMessage`** objects, set the maintype to `message`, and set the subtype to *subtype* if it is specified or `rfc822` if it is not. If *subtype* is `partial`, raise an error (`bytes` objects must be used to construct `message/partial` parts).

If *charset* is provided (which is valid only for `str`), encode the string to bytes using the specified character set. The default is `utf-8`. If the specified *charset* is a known alias for a standard MIME charset name, use the standard charset instead.

If *cte* is set, encode the payload using the specified content transfer encoding, and set the *Content-Transfer-Encoding* header to that value. Possible values for *cte* are `quoted-printable`, `base64`, `7bit`, `8bit`, and `binary`. If the input cannot be encoded in the specified encoding (for example, specifying a *cte* of `7bit` for an

input that contains non-ASCII values), raise a **ValueError**.

- For `str` objects, if *cte* is not set use heuristics to determine the most compact encoding.
- For **EmailMessage**, per **RFC 2046** [https://datatracker.ietf.org/doc/html/rfc2046.html], raise an error if a *cte* of `quoted-printable` or `base64` is requested for *subtype* `rfc822`, and for any *cte* other than `7bit` for *subtype* `external-body`. For `message/rfc822`, use `8bit` if *cte* is not specified. For all other values of *subtype*, use `7bit`.

Note

A *cte* of `binary` does not actually work correctly yet. The `EmailMessage` object as modified by `set_content` is correct, but **BytesGenerator** does not serialize it correctly.

If *disposition* is set, use it as the value of the *Content-Disposition* header. If not specified, and *filename* is specified, add the header with the value `attachment`. If *disposition* is not specified and *filename* is also not specified, do not add the header. The only valid values for *disposition* are `attachment` and `inline`.

If *filename* is specified, use it as the value of the `filename` parameter of the *Content-Disposition* header.

If *cid* is specified, add a *Content-ID* header with *cid* as its value.

If *params* is specified, iterate its `items` method and use the resulting `(key, value)` pairs to set additional parameters on the *Content-Type* header.

If *headers* is specified and is a list of strings of the form `headername: headervalue` or a list of `header` objects (distinguished from strings by having a `name` attribute), add the headers to *msg*.

Originally added in 3.4 as a provisional module

`email`: Examples

Here are a few examples of how to use the `email` package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message (both the text content and the addresses may contain unicode characters):

```
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.message import EmailMessage

# Open the plain text file whose name is in textfile for
with open(textfile) as fp:
    # Create a text/plain message
    msg = EmailMessage()
    msg.set_content(fp.read())

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = f'The contents of {textfile}'
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server.
s = smtplib.SMTP('localhost')
s.send_message(msg)
s.quit()
```

Parsing RFC 822 [https://datatracker.ietf.org/doc/html/rfc822.html] headers can easily be done by the using the classes from the `parser` module:

```
# Import the email modules we'll need
from email.parser import BytesParser, Parser
from email.policy import default

# If the e-mail headers are in a file, uncomment these t
# with open(messagefile, 'rb') as fp:
#     headers = BytesParser(policy=default).parse(fp)

#  Or for parsing headers in a string (this is an uncomm
headers = Parser(policy=default).parsestr(
        'From: Foo Bar <user@example.com>\n'
        'To: <someone_else@example.com>\n'
        'Subject: Test message\n'
        '\n'
        'Body would go here\n')

#  Now the header items can be accessed as a dictionary:
print('To: {}'.format(headers['to']))
print('From: {}'.format(headers['from']))
print('Subject: {}'.format(headers['subject']))

# You can also access the parts of the addresses:
print('Recipient username: {}'.format(headers['to'].addr
print('Sender name: {}'.format(headers['from'].addresses
```

Here's an example of how to send a MIME message containing a bunch of family pictures that may be residing in a directory:

```
# Import smtplib for the actual sending function.
import smtplib

# Here are the email package modules we'll need.
from email.message import EmailMessage

# Create the container email message.
msg = EmailMessage()
msg['Subject'] = 'Our family reunion'
# me == the sender's email address
# family = the list of all recipients' email addresses
```

```
msg['From'] = me
msg['To'] = ', '.join(family)
msg.preamble = 'You will not see this in a MIME-aware ma

# Open the files in binary mode.  You can also omit the
# if you want MIMEImage to guess it.
for file in pngfiles:
    with open(file, 'rb') as fp:
        img_data = fp.read()
    msg.add_attachment(img_data, maintype='image',
                                 subtype='png')

# Send the email via our own SMTP server.
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

Here's an example of how to send the entire contents of a directory as an email message: 1

```
#!/usr/bin/env python3

"""Send the contents of a directory as a MIME message.""

import os
import smtplib
# For guessing MIME type based on file name extension
import mimetypes

from argparse import ArgumentParser

from email.message import EmailMessage
from email.policy import SMTP

def main():
    parser = ArgumentParser(description="""\
Send the contents of a directory as a MIME message.
Unless the -o option is given, the email is sent by forw
SMTP server, which then does the normal delivery process
```

```
must be running an SMTP server.
""")
    parser.add_argument('-d', '--directory',
                        help="""Mail the contents of the
                        otherwise use the current direct
                        files in the directory are sent,
                        subdirectories.""")
    parser.add_argument('-o', '--output',
                        metavar='FILE',
                        help="""Print the composed messa
                        sending the message to the SMTP
    parser.add_argument('-s', '--sender', required=True,
                        help='The value of the From: hea
    parser.add_argument('-r', '--recipient', required=Tr
                        action='append', metavar='RECIPI
                        default=[], dest='recipients',
                        help='A To: header value (at lea
    args = parser.parse_args()
    directory = args.directory
    if not directory:
        directory = '.'
    # Create the message
    msg = EmailMessage()
    msg['Subject'] = f'Contents of directory {os.path.ab
    msg['To'] = ', '.join(args.recipients)
    msg['From'] = args.sender
    msg.preamble = 'You will not see this in a MIME-awar

    for filename in os.listdir(directory):
        path = os.path.join(directory, filename)
        if not os.path.isfile(path):
            continue
        # Guess the content type based on the file's ext
        # will be ignored, although we should check for
        # gzip'd or compressed files.
        ctype, encoding = mimetypes.guess_type(path)
        if ctype is None or encoding is not None:
            # No guess could be made, or the file is enc
```

```
            # use a generic bag-of-bits type.
            ctype = 'application/octet-stream'
        maintype, subtype = ctype.split('/', 1)
        with open(path, 'rb') as fp:
            msg.add_attachment(fp.read(),
                               maintype=maintype,
                               subtype=subtype,
                               filename=filename)
    # Now send or store the message
    if args.output:
        with open(args.output, 'wb') as fp:
            fp.write(msg.as_bytes(policy=SMTP))
    else:
        with smtplib.SMTP('localhost') as s:
            s.send_message(msg)

if __name__ == '__main__':
    main()
```

Here's an example of how to unpack a MIME message like the one above, into a directory of files:

```
#!/usr/bin/env python3

"""Unpack a MIME message into a directory of files."""

import os
import email
import mimetypes

from email.policy import default

from argparse import ArgumentParser

def main():
    parser = ArgumentParser(description="""\
Unpack a MIME message into a directory of files.
```

```
""")
    parser.add_argument('-d', '--directory', required=Tr
                        help="""Unpack the MIME message
                        directory, which will be created
                        exist.""")
    parser.add_argument('msgfile')
    args = parser.parse_args()

    with open(args.msgfile, 'rb') as fp:
        msg = email.message_from_binary_file(fp, policy=

    try:
        os.mkdir(args.directory)
    except FileExistsError:
        pass

    counter = 1
    for part in msg.walk():
        # multipart/* are just containers
        if part.get_content_maintype() == 'multipart':
            continue
        # Applications should really sanitize the given
        # email message can't be used to overwrite impor
        filename = part.get_filename()
        if not filename:
            ext = mimetypes.guess_extension(part.get_cor
            if not ext:
                # Use a generic bag-of-bits extension
                ext = '.bin'
            filename = f'part-{counter:03d}{ext}'
        counter += 1
        with open(os.path.join(args.directory, filename)
            fp.write(part.get_payload(decode=True))

if __name__ == '__main__':
    main()
```

Here's an example of how to create an HTML message with an

alternative plain text version. To make things a bit more interesting, we include a related image in the html part, and we save a copy of what we are going to send to disk, as well as sending it.

```
#!/usr/bin/env python3

import smtplib

from email.message import EmailMessage
from email.headerregistry import Address
from email.utils import make_msgid

# Create the base text message.
msg = EmailMessage()
msg['Subject'] = "Ayons asperges pour le déjeuner"
msg['From'] = Address("Pepé Le Pew", "pepe", "example.co
msg['To'] = (Address("Penelope Pussycat", "penelope", "e
             Address("Fabrette Pussycat", "fabrette", "e
msg.set_content("""\
Salut!

Cela ressemble à un excellent recipie[1] déjeuner.

[1] http://www.yummly.com/recipe/Roasted-Asparagus-Epicu

--Pepé
""")

# Add the html version.  This converts the message into
# container, with the original text message as the first
# message as the second part.
asparagus_cid = make_msgid()
msg.add_alternative("""\
<html>
  <head></head>
  <body>
    <p>Salut!</p>
    <p>Cela ressemble à un excellent
        <a href="http://www.yummly.com/recipe/Roasted-As
```

```
            recipie
        </a> déjeuner.
    </p>
    <img src="cid:{asparagus_cid}" />
  </body>
</html>
""".format(asparagus_cid=asparagus_cid[1:-1]), subtype='
# note that we needed to peel the <> off the msgid for u

# Now add the related image to the html part.
with open("roasted-asparagus.jpg", 'rb') as img:
    msg.get_payload()[1].add_related(img.read(), 'image'
                                     cid=asparagus_cid)

# Make a local copy of what we are going to send.
with open('outgoing.msg', 'wb') as f:
    f.write(bytes(msg))

# Send the message via local SMTP server.
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

If we were sent the message from the last example, here is one way we could process it:

```
import os
import sys
import tempfile
import mimetypes
import webbrowser

# Import the email modules we'll need
from email import policy
from email.parser import BytesParser

def magic_html_parser(html_text, partfiles):
    """Return safety-sanitized html linked to partfiles.
```

```
    Rewrite the href="cid:...." attributes to point to t
    Though not trivial, this should be possible using ht
    """
    raise NotImplementedError("Add the magic needed")

# In a real program you'd get the filename from the argu
with open('outgoing.msg', 'rb') as fp:
    msg = BytesParser(policy=policy.default).parse(fp)

# Now the header items can be accessed as a dictionary,
# be converted to unicode:
print('To:', msg['to'])
print('From:', msg['from'])
print('Subject:', msg['subject'])

# If we want to print a preview of the message content,
# the least formatted payload is and print the first thr
# if the message has no plain text part printing the fir
# is probably useless, but this is just a conceptual exa
simplest = msg.get_body(preferencelist=('plain', 'html')
print()
print(''.join(simplest.get_content().splitlines(keepends

ans = input("View full message?")
if ans.lower()[0] == 'n':
    sys.exit()

# We can extract the richest alternative in order to dis
richest = msg.get_body()
partfiles = {}
if richest['content-type'].maintype == 'text':
    if richest['content-type'].subtype == 'plain':
        for line in richest.get_content().splitlines():
            print(line)
        sys.exit()
    elif richest['content-type'].subtype == 'html':
        body = richest
```

```
    else:
        print("Don't know how to display {}".format(rich
        sys.exit()
elif richest['content-type'].content_type == 'multipart/
    body = richest.get_body(preferencelist=('html'))
    for part in richest.iter_attachments():
        fn = part.get_filename()
        if fn:
            extension = os.path.splitext(part.get_filena
        else:
            extension = mimetypes.guess_extension(part.g
        with tempfile.NamedTemporaryFile(suffix=extensio
            f.write(part.get_content())
            # again strip the <> to go from email form o
            partfiles[part['content-id'][1:-1]] = f.name
else:
    print("Don't know how to display {}".format(richest.
    sys.exit()
with tempfile.NamedTemporaryFile(mode='w', delete=False)
    f.write(magic_html_parser(body.get_content(), partfi
webbrowser.open(f.name)
os.remove(f.name)
for fn in partfiles.values():
    os.remove(fn)

# Of course, there are lots of email messages that could
# minded program, but it will handle the most common one
```

Up to the prompt, the output from the above is:

```
To: Penelope Pussycat <penelope@example.com>, Fabrette P
From: Pepé Le Pew <pepe@example.com>
Subject: Ayons asperges pour le déjeuner

Salut!

Cela ressemble à un excellent recipie[1] déjeuner.
```

Footnotes

Thanks to Matthew Dixon Cowles for the original inspiration and examples.

`email.message.Message`: Representing an email message using the `compat32` API

The `Message` class is very similar to the `EmailMessage` class, without the methods added by that class, and with the default behavior of certain other methods being slightly different. We also document here some methods that, while supported by the `EmailMessage` class, are not recommended unless you are dealing with legacy code.

The philosophy and structure of the two classes is otherwise the same.

This document describes the behavior under the default (for `Message`) policy `Compat32`. If you are going to use another policy, you should be using the `EmailMessage` class instead.

An email message consists of *headers* and a *payload*. Headers must be **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html] style names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as *multipart/** or *message/rfc822*.

The conceptual model provided by a `Message` object is that of an ordered dictionary of headers with additional methods for accessing both specialized information from the headers, for accessing the payload, for generating a serialized version of the message, and for recursively walking over the object tree. Note that duplicate headers are supported but special methods must be used to access them.

The **Message** pseudo-dictionary is indexed by the header names, which must be ASCII values. The values of the dictionary are strings that are supposed to contain only ASCII characters; there is some special handling for non-ASCII input, but it doesn't always produce the correct results. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. There may also be a single envelope header, also known as the *Unix-From* header or the `From_` header. The *payload* is either a string or bytes, in the case of simple message objects, or a list of **Message** objects, for MIME container documents (e.g. *multipart/** and *message/rfc822*).

Here are the methods of the **Message** class:

class email.message.Message(*policy=compat32*)

If *policy* is specified (it must be an instance of a **policy** class) use the rules it specifies to update and serialize the representation of the message. If *policy* is not set, use the **compat32** policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the **policy** documentation.

Changed in version 3.3: The *policy* keyword argument was added.

as_string(*unixfrom=False*, *maxheaderlen=0*, *policy=None*)

Return the entire message flattened as a string. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. For backward compatibility reasons, *maxheaderlen* defaults to `0`, so if you want a different value you must override it explicitly (the value specified for *max_line_length* in the policy will be ignored by this method). The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the `Generator`.

Flattening the message may trigger changes to the

Message if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with `From` that is required by the Unix mbox format. For more flexibility, instantiate a **Generator** instance and use its **flatten()** method directly. For example:

```
from io import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=True, maxheaderl
g.flatten(msg)
text = fp.getvalue()
```

If the message object contains binary data that is not encoded according to RFC standards, the non-compliant data will be replaced by unicode "unknown character" code points. (See also **as_bytes()** and **BytesGenerator**.)

Changed in version 3.4: the *policy* keyword argument was added.

str()

Equivalent to **as_string()**. Allows `str(msg)` to produce a string containing the formatted message.

as_bytes(*unixfrom*=*False*, *policy*=*None*)

Return the entire message flattened as a bytes object. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting

produced by the method, since the specified *policy* will be passed to the `BytesGenerator`.

Flattening the message may trigger changes to the **`Message`** if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with `From` that is required by the Unix mbox format. For more flexibility, instantiate a **`BytesGenerator`** instance and use its **`flatten()`** method directly. For example:

```
from io import BytesIO
from email.generator import BytesGenerator
fp = BytesIO()
g = BytesGenerator(fp, mangle_from_=True, maxhe
g.flatten(msg)
text = fp.getvalue()
```

New in version 3.4.

bytes()

Equivalent to **`as_bytes()`**. Allows `bytes(msg)` to produce a bytes object containing the formatted message.

New in version 3.4.

is_multipart()

Return `True` if the message's payload is a list of sub-**`Message`** objects, otherwise return `False`. When **`is_multipart()`** returns `False`, the payload should be a string object (which might be a CTE encoded binary payload). (Note that **`is_multipart()`** returning `True` does not necessarily mean that

"msg.get_content_maintype() == 'multipart'" will return the `True`. For example, `is_multipart` will return `True` when the **`Message`** is of type `message/rfc822`.)

set_unixfrom(*unixfrom*)

Set the message's envelope header to *unixfrom*, which should be a string.

get_unixfrom()

Return the message's envelope header. Defaults to `None` if the envelope header was never set.

attach(*payload*)

Add the given *payload* to the current payload, which must be `None` or a list of **`Message`** objects before the call. After the call, the payload will always be a list of **`Message`** objects. If you want to set the payload to a scalar object (e.g. a string), use **`set_payload()`** instead.

This is a legacy method. On the **`EmailMessage`** class its functionality is replaced by **`set_content()`** and the related `make` and `add` methods.

get_payload(*i=None*, *decode=False*)

Return the current payload, which will be a list of **`Message`** objects when **`is_multipart()`** is `True`, or a string when **`is_multipart()`** is `False`. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument *i*, **`get_payload()`** will return the *i*-th element of the payload, counting from zero, if **`is_multipart()`** is `True`. An **`IndexError`** will be raised if *i* is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. **`is_multipart()`** is `False`) and *i* is

given, a **TypeError** is raised.

Optional *decode* is a flag indicating whether the payload should be decoded or not, according to the *Content-Transfer-Encoding* header. When `True` and the message is not a multipart, the payload will be decoded if this header's value is `quoted-printable` or `base64`. If some other encoding is used, or *Content-Transfer-Encoding* header is missing, the payload is returned as-is (undecoded). In all cases the returned value is binary data. If the message is a multipart and the *decode* flag is `True`, then `None` is returned. If the payload is base64 and it was not perfectly formed (missing padding, characters outside the base64 alphabet), then an appropriate defect will be added to the message's defect property (**InvalidBase64PaddingDefect** or **InvalidBase64CharactersDefect**, respectively).

When *decode* is `False` (the default) the body is returned as a string without decoding the *Content-Transfer-Encoding*. However, for a *Content-Transfer-Encoding* of 8bit, an attempt is made to decode the original bytes using the `charset` specified by the *Content-Type* header, using the `replace` error handler. If no `charset` is specified, or if the `charset` given is not recognized by the email package, the body is decoded using the default ASCII charset.

This is a legacy method. On the **EmailMessage** class its functionality is replaced by **get_content()** and **iter_parts()**.

set_payload(*payload*, *charset=None*)

Set the entire message object's payload to *payload*. It is the client's responsibility to ensure the payload invariants. Optional *charset* sets the message's default character set; see **set_charset()** for details.

This is a legacy method. On the **EmailMessage** class

its functionality is replaced by **set_content()**.

set_charset(*charset*)

Set the character set of the payload to *charset*, which can either be a **Charset** instance (see **email.charset**), a string naming a character set, or None. If it is a string, it will be converted to a **Charset** instance. If *charset* is None, the charset parameter will be removed from the *Content-Type* header (the message will not be otherwise modified). Anything else will generate a **TypeError**.

If there is no existing *MIME-Version* header one will be added. If there is no existing *Content-Type* header, one will be added with a value of *text/plain*. Whether the *Content-Type* header already exists or not, its charset parameter will be set to *charset.output_charset*. If *charset.input_charset* and *charset.output_charset* differ, the payload will be re-encoded to the *output_charset*. If there is no existing *Content-Transfer-Encoding* header, then the payload will be transfer-encoded, if needed, using the specified **Charset**, and a header with the appropriate value will be added. If a *Content-Transfer-Encoding* header already exists, the payload is assumed to already be correctly encoded using that *Content-Transfer-Encoding* and is not modified.

This is a legacy method. On the **EmailMessage** class its functionality is replaced by the *charset* parameter of the **email.emailmessage.EmailMessage.set_content()** method.

get_charset()

Return the **Charset** instance associated with the message's payload.

This is a legacy method. On the **EmailMessage** class it always returns None.

The following methods implement a mapping-like interface for accessing the message's **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html] headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by **`keys()`**, but in a **`Message`** object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

In a model generated from bytes, any header values that (in contravention of the RFCs) contain non-ASCII bytes will, when retrieved through this interface, be represented as **`Header`** objects with a charset of `unknown-8bit`.

len()

Return the total number of headers, including duplicates.

contains(*name*)

Return `True` if the message object has a field named *name*. Matching is done case-insensitively and *name* should not include the trailing colon. Used for the `in` operator, e.g.:

```
if 'message-id' in myMessage:
   print('Message-ID:', myMessage['message-id']
```

getitem(*name*)

Return the value of the named header field. *name*

should not include the colon field separator. If the header is missing, `None` is returned; a **`KeyError`** is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the **`get_all()`** method to get the values of all the extant named headers.

setitem(*name*, *val*)

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing fields.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

delitem(*name*)

Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

keys()

Return a list of all the message's header field names.

values()

Return a list of all the message's field values.

items()

Return a list of 2-tuples containing all the message's field headers and values.

get(*name*, *failobj*=*None*)

Return the value of the named header field. This is identical to `__getitem__()` except that optional *failobj* is returned if the named header is missing (defaults to `None`).

Here are some additional useful methods:

get_all(*name*, *failobj*=*None*)

Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to `None`).

add_header(*_name*, *_value*, ***_params*)

Extended header setting. This method is similar to `__setitem__()` except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as `key="value"` unless the value is `None`, in which case only the key will be added. If the value contains non-ASCII characters, it can be specified as a three tuple in the format `(CHARSET, LANGUAGE, VALUE)`, where `CHARSET` is a string naming the charset to be used to encode the value, `LANGUAGE` can usually be set to `None` or the empty string (see **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html] for other possibilities), and `VALUE` is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html] format using a `CHARSET` of `utf-8` and a `LANGUAGE` of `None`.

Here's an example:

```
msg.add_header('Content-Disposition', 'attachme
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.
```

An example with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachme
               filename=('iso-8859-1', '', 'Fuß
```

Which produces

```
Content-Disposition: attachment; filename*="iso
```

replace_header(*_name*, *_value*)

Replace a header. Replace the first header found in the message that matches *_name*, retaining header order and field name case. If no matching header was found, a **`KeyError`** is raised.

get_content_type()

Return the message's content type. The returned string is coerced to lower case of the form *maintype/subtype*. If there was no *Content-Type* header in the message the default type as given by **`get_default_type()`** will be returned. Since according to **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html], messages always have a default type, **`get_content_type()`** will always return a value.

RFC 2045 [https://datatracker.ietf.org/doc/html/rfc2045.html] defines a message's default type to be *text/plain* unless it appears inside a *multipart/digest* container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html] mandates that the default type be *text/plain*.

get_content_maintype()

Return the message's main content type. This is the *maintype* part of the string returned by **`get_content_type()`**.

get_content_subtype()

Return the message's sub-content type. This is the *subtype* part of the string returned by **`get_content_type()`**.

get_default_type()

Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

set_default_type(*ctype*)

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header.

get_params(*failobj*=*None*, *header*='content-type', *unquote*=*True*)

Return the message's *Content-Type* parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the `'='` sign. The left hand side of the `'='` is the key, while the right hand side is the value. If there is no `'='` sign in the parameter the value is the empty string, otherwise the value is as described in **`get_param()`** and is unquoted if optional *unquote* is `True` (the default).

Optional *failobj* is the object to return if there is no *Content-Type* header. Optional *header* is the header to search instead of *Content-Type*.

This is a legacy method. On the **EmailMessage** class its functionality is replaced by the *params* property of the individual header objects returned by the header access methods.

get_param(*param*, *failobj*=*None*, *header*='content-type', *unquote*=*True*)

Return the value of the *Content-Type* header's parameter *param* as a string. If the message has no *Content-Type* header or if there is no such parameter, then *failobj* is returned (defaults to `None`).

Optional *header* if given, specifies the message header to use instead of *Content-Type*.

Parameter keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html] encoded. When it's a 3-tuple, the elements of the value are of the form `(CHARSET, LANGUAGE, VALUE)`. Note that both `CHARSET` and `LANGUAGE` can be `None`, in which case you should consider `VALUE` to be encoded in the `us-ascii` charset. You can usually ignore `LANGUAGE`.

If your application doesn't care whether the parameter was encoded as in **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html], you can collapse the parameter value by calling **email.utils.collapse_rfc2231_value()**, passing in the return value from **get_param()**. This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn't. For example:

```
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawp
```

In any case, the parameter value (either the returned string, or the `VALUE` item in the 3-tuple) is always

unquoted, unless *unquote* is set to `False`.

This is a legacy method. On the **`EmailMessage`** class its functionality is replaced by the *params* property of the individual header objects returned by the header access methods.

set_param(*param*, *value*, *header*='Content-Type', *requote*=True, *charset*=None, *language*='', *replace*=False)

Set a parameter in the *Content-Type* header. If the parameter already exists in the header, its value will be replaced with *value*. If the *Content-Type* header as not yet been defined for this message, it will be set to *text/plain* and the new parameter value will be appended as per **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html].

Optional *header* specifies an alternative header to *Content-Type*, and all parameters will be quoted as necessary unless optional *requote* is `False` (the default is `True`).

If optional *charset* is specified, the parameter will be encoded according to **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html]. Optional *language* specifies the RFC 2231 language, defaulting to the empty string. Both *charset* and *language* should be strings.

If *replace* is `False` (the default) the header is moved to the end of the list of headers. If *replace* is `True`, the header will be updated in place.

Changed in version 3.4: `replace` keyword was added.

del_param(*param*, *header*='content-type', *requote*=True)

Remove the given parameter completely from the *Content-Type* header. The header will be re-written in place without the parameter or its value. All values will be quoted as necessary unless *requote* is `False` (the

default is `True`). Optional *header* specifies an alternative to *Content-Type*.

set_type(*type*, *header*='Content-Type', *requote*=*True*)

Set the main type and subtype for the *Content-Type* header. *type* must be a string in the form *maintype/subtype*, otherwise a **`ValueError`** is raised.

This method replaces the *Content-Type* header, keeping all the parameters in place. If *requote* is `False`, this leaves the existing header's quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the *header* argument. When the *Content-Type* header is set a *MIME-Version* header is also added.

This is a legacy method. On the **`EmailMessage`** class its functionality is replaced by the `make_` and `add_` methods.

get_filename(*failobj*=*None*)

Return the value of the `filename` parameter of the *Content-Disposition* header of the message. If the header does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per **`email.utils.unquote()`**.

get_boundary(*failobj*=*None*)

Return the value of the `boundary` parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per **`email.utils.unquote()`**.

set_boundary(*boundary*)

Set the `boundary` parameter of the *Content-Type* header to *boundary*. **`set_boundary()`** will always quote *boundary* if necessary. A **`HeaderParseError`** is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different than deleting the old *Content-Type* header and adding a new one with the new boundary via **`add_header()`**, because **`set_boundary()`** preserves the order of the *Content-Type* header in the list of headers. However, it does *not* preserve any continuation lines which may have been present in the original *Content-Type* header.

get_content_charset(*failobj* = *None*)

Return the `charset` parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no `charset` parameter, *failobj* is returned.

Note that this method differs from **`get_charset()`** which returns the **`Charset`** instance for the default encoding of the message body.

get_charsets(*failobj* = *None*)

Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the *Content-Type* header for the represented subpart. However, if the subpart has no *Content-Type* header, no `charset` parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

get_content_disposition()

Return the lowercased value (without parameters) of the message's *Content-Disposition* header if it has one, or `None`. The possible values for this method are *inline*, *attachment* or `None` if the message follows **RFC 2183** [https://datatracker.ietf.org/doc/html/rfc2183.html].

New in version 3.5.

walk()

The **`walk()`** method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use **`walk()`** as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```

`walk` iterates over the subparts of any part where **`is_multipart()`** returns `True`, even though `msg.get_content_maintype() == 'multipart'` may return `False`. We can see this in our example by making use of the `_structure` debug helper function:

```
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'm
...           part.is_multipart())
True True
False False
False True
```

```
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
    text/plain
    message/delivery-status
        text/plain
        text/plain
    message/rfc822
        text/plain
```

Here the `message` parts are not `multiparts`, but they do contain subparts. `is_multipart()` returns `True` and `walk` descends into the subparts.

`Message` objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

preamble

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the **`Parser`** discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the **`Generator`** is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See **`email.parser`** and

email.generator for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

epilogue

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message.

You do not need to set the epilogue to the empty string in order for the **Generator** to print a newline at the end of the file.

defects

The *defects* attribute contains a list of all the problems found when parsing this message. See **email.errors** for a detailed description of the possible parsing defects.

email.mime: Creating email and MIME objects from scratch

Source code: Lib/email/mime/ [https://github.com/python/cpython/tree/3.11/Lib/email/mime/]

This module is part of the legacy (`Compat32`) email API. Its functionality is partially replaced by the **contentmanager** in the new API, but in certain applications these classes may still be useful, even in non-legacy code.

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual **Message** objects by hand. In fact, you can also take an existing structure and add new **Message** objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating **Message** instances, adding attachments and all the appropriate headers manually. For MIME messages though, the **email** package provides some convenient subclasses to make things easier.

Here are the classes:

class email.mime.base.MIMEBase(*_maintype*, *_subtype*, *, *policy*=*compat32*, ***_params*)

Module: **email.mime.base**

This is the base class for all the MIME-specific subclasses of **Message**. Ordinarily you won't create instances specifically of **MIMEBase**, although you could. **MIMEBase** is provided primarily as a convenient base class for more specific MIME-

aware subclasses.

_maintype is the *Content-Type* major type (e.g. *text* or *image*), and *_subtype* is the *Content-Type* minor type (e.g. *plain* or *gif*). *_params* is a parameter key/value dictionary and is passed directly to **`Message.add_header`**.

If *policy* is specified, (defaults to the **`compat32`** policy) it will be passed to **`Message`**.

The **`MIMEBase`** class always adds a *Content-Type* header (based on *_maintype*, *_subtype*, and *_params*), and a *MIME-Version* header (always set to `1.0`).

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.nonmultipart.MIMENonMultipart

Module: **`email.mime.nonmultipart`**

A subclass of **`MIMEBase`**, this is an intermediate base class for MIME messages that are not *multipart*. The primary purpose of this class is to prevent the use of the **`attach()`** method, which only makes sense for *multipart* messages. If **`attach()`** is called, a **`MultipartConversionError`** exception is raised.

class email.mime.multipart.MIMEMultipart(*_subtype='mixed'*, *boundary=None*, *_subparts=None*, ***, *policy=compat32*, ***_params*)

Module: **`email.mime.multipart`**

A subclass of **`MIMEBase`**, this is an intermediate base class for MIME messages that are *multipart*. Optional *_subtype* defaults to *mixed*, but can be used to specify the subtype of the message. A *Content-Type* header of *multipart/_subtype* will be added to the message object. A *MIME-Version* header will also be added.

Optional *boundary* is the multipart boundary string. When `None` (the default), the boundary is calculated when needed (for example, when the message is serialized).

_subparts is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the **`Message.attach`** method.

Optional *policy* argument defaults to **`compat32`**.

Additional parameters for the *Content-Type* header are taken from the keyword arguments, or passed into the *_params* argument, which is a keyword dictionary.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.application.MIMEApplication(*_data*, *_subtype='octet-stream'*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

Module: **`email.mime.application`**

A subclass of **`MIMENonMultipart`**, the **`MIMEApplication`** class is used to represent MIME message objects of major type *application*. *_data* is a string containing the raw byte data. Optional *_subtype* specifies the MIME subtype and defaults to *octet-stream*.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the data for transport. This callable takes one argument, which is the **`MIMEApplication`** instance. It should use **`get_payload()`** and **`set_payload()`** to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the **`email.encoders`** module for a list of the built-in encoders.

Optional *policy* argument defaults to **`compat32`**.

_params are passed straight through to the base class constructor.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.audio.MIMEAudio(*_audiodata*, *_subtype=None*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

Module: **email.mime.audio**

A subclass of **MIMENonMultipart**, the **MIMEAudio** class is used to create MIME message objects of major type *audio*. *_audiodata* is a string containing the raw audio data. If this data can be decoded as au, wav, aiff, or aifc, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the audio subtype via the *_subtype* argument. If the minor type could not be guessed and *_subtype* was not given, then **TypeError** is raised.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the **MIMEAudio** instance. It should use **get_payload()** and **set_payload()** to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the **email.encoders** module for a list of the built-in encoders.

Optional *policy* argument defaults to **compat32**.

_params are passed straight through to the base class constructor.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.image.MIMEImage(*_imagedata*, *_subtype=None*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

Module: **email.mime.image**

A subclass of **MIMENonMultipart**, the **MIMEImage** class is used to create MIME message objects of major type *image*. *_imagedata* is a string containing the raw image data. If this data type can be detected (jpeg, png, gif, tiff, rgb, pbm, pgm,

ppm, rast, xbm, bmp, webp, and exr attempted), then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the image subtype via the *_subtype* argument. If the minor type could not be guessed and *_subtype* was not given, then **TypeError** is raised.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable takes one argument, which is the **MIMEImage** instance. It should use **get_payload()** and **set_payload()** to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the **email.encoders** module for a list of the built-in encoders.

Optional *policy* argument defaults to **compat32**.

_params are passed straight through to the **MIMEBase** constructor.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.message.MIMEMessage(*_msg*, *_subtype='rfc822'*, ***, *policy=compat32*)

Module: **email.mime.message**

A subclass of **MIMENonMultipart**, the **MIMEMessage** class is used to create MIME objects of main type *message*. *_msg* is used as the payload, and must be an instance of class **Message** (or a subclass thereof), otherwise a **TypeError** is raised.

Optional *_subtype* sets the subtype of the message; it defaults to *rfc822*.

Optional *policy* argument defaults to **compat32**.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.text.MIMEText(*_text*, *_subtype='plain'*, *_charset=None*, ***, *policy=compat32*)

Module: **email.mime.text**

A subclass of **MIMENonMultipart**, the **MIMEText** class is used to create MIME objects of major type *text*. *_text* is the string for the payload. *_subtype* is the minor type and defaults to *plain*. *_charset* is the character set of the text and is passed as an argument to the **MIMENonMultipart** constructor; it defaults to `us-ascii` if the string contains only `ascii` code points, and `utf-8` otherwise. The *_charset* parameter accepts either a string or a **Charset** instance.

Unless the *_charset* argument is explicitly set to `None`, the MIMEText object created will have both a *Content-Type* header with a `charset` parameter, and a *Content-Transfer-Encoding* header. This means that a subsequent `set_payload` call will not result in an encoded payload, even if a charset is passed in the `set_payload` command. You can "reset" this behavior by deleting the `Content-Transfer-Encoding` header, after which a `set_payload` call will automatically encode the new payload (and add a new *Content-Transfer-Encoding* header).

Optional *policy* argument defaults to **compat32**.

Changed in version 3.5: *_charset* also accepts **Charset** instances.

Changed in version 3.6: Added *policy* keyword-only parameter.

`email.header`: Internationalized headers

Source code: Lib/email/header.py [https://github.com/python/cpython/tree/3.11/Lib/email/header.py]

This module is part of the legacy (`Compat32`) email API. In the current API encoding and decoding of headers is handled transparently by the dictionary-like API of the `EmailMessage` class. In addition to uses in legacy code, this module can be useful in applications that need to completely control the character sets used when encoding headers.

The remaining text in this section is the original documentation of the module.

RFC 2822 [https://datatracker.ietf.org/doc/html/rfc2822.html] is the base standard that describes the format of email messages. It derives from the older **RFC 822** [https://datatracker.ietf.org/doc/html/rfc822.html] standard which came into widespread use at a time when most email was composed of ASCII characters only. **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html] is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html]-compliant format. These RFCs include **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html], **RFC 2046** [https://datatracker.ietf.org/doc/html/rfc2046.html], **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html], and **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html]. The `email` package supports

these standards in its **email.header** and **email.charset** modules.

If you want to include non-ASCII characters in your email headers, say in the *Subject* or *To* fields, you should use the **Header** class and assign the field in the **Message** object to an instance of **Header** instead of using a string for the header value. Import the **Header** class from the **email.header** module. For example:

```
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> msg.as_string()
'Subject: =?iso-8859-1?q?p=F6stal?=\n\n'
```

Notice here how we wanted the *Subject* field to contain a non-ASCII character? We did this by creating a **Header** instance and passing in the character set that the byte string was encoded in. When the subsequent **Message** instance was flattened, the *Subject* field was properly **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html] encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

Here is the **Header** class description:

class email.header.Header(*s=None*, *charset=None*, *maxlinelen=None*, *header_name=None*, *continuation_ws=' '*, *errors='strict'*)

Create a MIME-compliant header that can contain strings in different character sets.

Optional *s* is the initial header value. If `None` (the default), the initial header value is not set. You can later append to the header with **append()** method calls. *s* may be an instance of **bytes** or **str**, but see the **append()** documentation for semantics.

Optional *charset* serves two purposes: it has the same meaning

as the *charset* argument to the **append()** method. It also sets the default character set for all subsequent **append()** calls that omit the *charset* argument. If *charset* is not provided in the constructor (the default), the `us-ascii` character set is used both as *s*'s initial charset and as the default for subsequent **append()** calls.

The maximum line length can be specified explicitly via *maxlinelen*. For splitting the first line to a shorter value (to account for the field header which isn't included in *s*, e.g. *Subject*) pass in the name of the field in *header_name*. The default *maxlinelen* is 76, and the default value for *header_name* is `None`, meaning it is not taken into account for the first line of a long, split header.

Optional *continuation_ws* must be **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html]-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. *continuation_ws* defaults to a single space character.

Optional *errors* is passed straight through to the **append()** method.

append(*s*, *charset*=*None*, *errors*='*strict*')

Append the string *s* to the MIME header.

Optional *charset*, if given, should be a **Charset** instance (see **email.charset**) or the name of a character set, which will be converted to a **Charset** instance. A value of `None` (the default) means that the *charset* given in the constructor is used.

s may be an instance of **bytes** or **str**. If it is an instance of **bytes**, then *charset* is the encoding of that byte string, and a **UnicodeError** will be raised if the string cannot be decoded with that character set.

If *s* is an instance of **str**, then *charset* is a hint specifying the character set of the characters in the string.

In either case, when producing an **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html]-compliant header using **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html] rules, the string will be encoded using the output codec of the charset. If the string cannot be encoded using the output codec, a UnicodeError will be raised.

Optional *errors* is passed as the errors argument to the decode call if *s* is a byte string.

encode(*splitchars*=*';, \t'*, *maxlinelen*=*None*, *linesep*=*'\n'*)

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings.

Optional *splitchars* is a string containing characters which should be given extra weight by the splitting algorithm during normal header wrapping. This is in very rough support of **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html]'s 'higher level syntactic breaks': split points preceded by a splitchar are preferred during line splitting, with the characters preferred in the order in which they appear in the string. Space and tab may be included in the string to indicate whether preference should be given to one over the other as a split point when other split chars do not appear in the line being split. Splitchars does not affect **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html] encoded lines.

maxlinelen, if given, overrides the instance's value for the maximum line length.

linesep specifies the characters used to separate the lines of the folded header. It defaults to the most useful value for Python application code (`\n`), but `\r\n` can be specified in order to produce headers with RFC-compliant line separators.

Changed in version 3.2: Added the *linesep* argument.

The **Header** class also provides a number of methods to support standard operators and built-in functions.

__str__()

Returns an approximation of the **Header** as a string, using an unlimited line length. All pieces are converted to unicode using the specified encoding and joined together appropriately. Any pieces with a charset of `'unknown-8bit'` are decoded as ASCII using the `'replace'` error handler.

Changed in version 3.2: Added handling for the `'unknown-8bit'` charset.

__eq__(*other*)

This method allows you to compare two **Header** instances for equality.

__ne__(*other*)

This method allows you to compare two **Header** instances for inequality.

The **email.header** module also provides the following convenient functions.

email.header.decode_header(*header*)

Decode a message header value without converting the character set. The header value is in *header*.

This function returns a list of `(decoded_string, charset)` pairs containing each of the decoded parts of the header. *charset* is `None` for non-encoded parts of the header, otherwise a lower case string containing the name of the character set specified in the encoded string.

Here's an example:

```
>>> from email.header import decode_header
>>> decode_header('=?iso-8859-1?q?p=F6stal?=')
[(b'p\xf6stal', 'iso-8859-1')]
```

email.header.make_header(*decoded_seq*, *maxlinelen=None*, *header_name=None*, *continuation_ws=' '*)

Create a **Header** instance from a sequence of pairs as returned by **decode_header()**.

decode_header() takes a header value string and returns a sequence of pairs of the format `(decoded_string, charset)` where *charset* is the name of the character set.

This function takes one of those sequence of pairs and returns a **Header** instance. Optional *maxlinelen*, *header_name*, and *continuation_ws* are as in the **Header** constructor.

`email.charset`: Representing character sets

Source code: Lib/email/charset.py [https://github.com/python/cpython/tree/3.11/Lib/email/charset.py]

This module is part of the legacy (`Compat32`) email API. In the new API only the aliases table is used.

The remaining text in this section is the original documentation of the module.

This module provides a class **`Charset`** for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of **`Charset`** are used in several other modules within the **`email`** package.

Import this class from the **`email.charset`** module.

class email.charset.Charset(*input_charset=DEFAULT_CHARSET*)

Map character sets to their email properties.

This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.

Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional *input_charset* is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if *input_charset* is `iso-8859-1`, then headers and bodies will be encoded using quoted-printable and no output conversion codec is necessary. If *input_charset* is `euc-jp`, then headers will be encoded with base64, bodies will not be encoded, but output text will be converted from the `euc-jp` character set to the `iso-2022-jp` character set.

`Charset` instances have the following data attributes:

input_charset

> The initial character set specified. Common aliases are converted to their *official* email names (e.g. `latin_1` is converted to `iso-8859-1`). Defaults to 7-bit `us-ascii`.

header_encoding

> If the character set must be encoded before it can be used in an email header, this attribute will be set to `Charset.QP` (for quoted-printable), `Charset.BASE64` (for base64 encoding), or `Charset.SHORTEST` for the shortest of QP or BASE64 encoding. Otherwise, it will be `None`.

body_encoding

> Same as *header_encoding*, but describes the encoding for the mail message's body, which indeed may be different than the header encoding. `Charset.SHORTEST` is not allowed for *body_encoding*.

output_charset

> Some character sets must be converted before they can be used in email headers or bodies. If the *input_charset* is one of them, this attribute will contain the name of the character set output will be converted to.

Otherwise, it will be `None`.

input_codec

The name of the Python codec used to convert the *input_charset* to Unicode. If no conversion codec is necessary, this attribute will be `None`.

output_codec

The name of the Python codec used to convert Unicode to the *output_charset*. If no conversion codec is necessary, this attribute will have the same value as the *input_codec*.

`Charset` instances also have the following methods:

get_body_encoding()

Return the content transfer encoding used for body encoding.

This is either the string `quoted-printable` or `base64` depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the Message object being encoded. The function should then set the *Content-Transfer-Encoding* header itself to whatever is appropriate.

Returns the string `quoted-printable` if *body_encoding* is `QP`, returns the string `base64` if *body_encoding* is `BASE64`, and returns the string `7bit` otherwise.

get_output_charset()

Return the output character set.

This is the *output_charset* attribute if that is not `None`, otherwise it is *input_charset*.

header_encode(*string*)

Header-encode the string *string*.

The type of encoding (base64 or quoted-printable) will be based on the *header_encoding* attribute.

header_encode_lines(*string*, *maxlengths*)

Header-encode a *string* by converting it first to bytes.

This is similar to **`header_encode()`** except that the string is fit into maximum line lengths as given by the argument *maxlengths*, which must be an iterator: each element returned from this iterator will provide the next maximum line length.

body_encode(*string*)

Body-encode the string *string*.

The type of encoding (base64 or quoted-printable) will be based on the *body_encoding* attribute.

The **`Charset`** class also provides a number of methods to support standard operations and built-in functions.

str()

Returns *input_charset* as a string coerced to lower case. **`__repr__()`** is an alias for **`__str__()`**.

_eq_(*other*)

This method allows you to compare two **`Charset`** instances for equality.

_ne_(*other*)

This method allows you to compare two **`Charset`** instances for inequality.

The **`email.charset`** module also provides the following functions

for adding new entries to the global character set, alias, and codec registries:

email.charset.add_charset(*charset*, *header_enc* = *None*, *body_enc* = *None*, *output_charset* = *None*)

Add character properties to the global registry.

charset is the input character set, and must be the canonical name of a character set.

Optional *header_enc* and *body_enc* is either `Charset.QP` for quoted-printable, `Charset.BASE64` for base64 encoding, `Charset.SHORTEST` for the shortest of quoted-printable or base64 encoding, or `None` for no encoding. `SHORTEST` is only valid for *header_enc*. The default is `None` for no encoding.

Optional *output_charset* is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method **`Charset.convert()`** is called. The default is to output in the same character set as the input.

Both *input_charset* and *output_charset* must have Unicode codec entries in the module's character set-to-codec mapping; use **`add_codec()`** to add codecs the module does not know about. See the **`codecs`** module's documentation for more information.

The global character set registry is kept in the module global dictionary `CHARSETS`.

email.charset.add_alias(*alias*, *canonical*)

Add a character set alias. *alias* is the alias name, e.g. `latin-1`. *canonical* is the character set's canonical name, e.g. `iso-8859-1`.

The global charset alias registry is kept in the module global dictionary `ALIASES`.

email.charset.add_codec(*charset*, *codecname*)

Add a codec that map characters in the given character set to and from Unicode.

charset is the canonical name of a character set. *codecname* is the name of a Python codec, as appropriate for the second argument to the `str`'s `encode()` method.

email.encoders: Encoders

Source code: Lib/email/encoders.py [https://github.com/python/cpython/tree/3.11/Lib/email/encoders.py]

This module is part of the legacy (`Compat32`) email API. In the new API the functionality is provided by the *cte* parameter of the `set_content()` method.

This module is deprecated in Python 3. The functions provided here should not be called explicitly since the `MIMEText` class sets the content type and CTE header using the *_subtype* and *_charset* values passed during the instantiation of that class.

The remaining text in this section is the original documentation of the module.

When creating `Message` objects from scratch, you often need to encode the payloads for transport through compliant mail servers. This is especially true for *image/** and *text/** type messages containing binary data.

The `email` package provides some convenient encoders in its **`encoders`** module. These encoders are actually used by the `MIMEAudio` and `MIMEImage` class constructors to provide default encodings. All encoder functions take exactly one argument, the message object to encode. They usually extract the payload, encode it, and reset the payload to this newly encoded value. They should also set the *Content-Transfer-Encoding* header as appropriate.

Note that these functions are not meaningful for a multipart message. They must be applied to individual subparts instead, and will raise a `TypeError` if passed a message whose type is multipart.

Here are the encoding functions provided:

email.encoders.encode_quopri(*msg*)

Encodes the payload into quoted-printable form and sets the *Content-Transfer-Encoding* header to `quoted-printable` [1]. This is a good encoding to use when most of your payload is normal printable data, but contains a few unprintable characters.

email.encoders.encode_base64(*msg*)

Encodes the payload into base64 form and sets the *Content-Transfer-Encoding* header to `base64`. This is a good encoding to use when most of your payload is unprintable data since it is a more compact form than quoted-printable. The drawback of base64 encoding is that it renders the text non-human readable.

email.encoders.encode_7or8bit(*msg*)

This doesn't actually modify the message's payload, but it does set the *Content-Transfer-Encoding* header to either `7bit` or `8bit` as appropriate, based on the payload data.

email.encoders.encode_noop(*msg*)

This does nothing; it doesn't even set the *Content-Transfer-Encoding* header.

Footnotes

[1]

Note that encoding with **`encode_quopri()`** also encodes all tabs and space characters in the data.

`email.utils`: Miscellaneous utilities

Source code: Lib/email/utils.py [https://github.com/python/cpython/tree/3.11/Lib/email/utils.py]

There are a couple of useful utilities provided in the `email.utils` module:

email.utils.localtime(*dt=None*)

Return local time as an aware datetime object. If called without arguments, return current time. Otherwise *dt* argument should be a `datetime` instance, and it is converted to the local time zone according to the system time zone database. If *dt* is naive (that is, `dt.tzinfo` is `None`), it is assumed to be in local time. In this case, a positive or zero value for *isdst* causes `localtime` to presume initially that summer time (for example, Daylight Saving Time) is or is not (respectively) in effect for the specified time. A negative value for *isdst* causes the `localtime` to attempt to divine whether summer time is in effect for the specified time.

New in version 3.3.

email.utils.make_msgid(*idstring=None*, *domain=None*)

Returns a string suitable for an **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html]-compliant *Message-ID* header. Optional *idstring* if given, is a string used to strengthen the uniqueness of the message id. Optional *domain* if given provides the portion of the msgid after the '@'. The default is the local hostname. It is not normally necessary to override this default, but may be useful certain cases, such as a constructing distributed system that uses a consistent domain name across multiple hosts.

Changed in version 3.2: Added the *domain* keyword.

The remaining functions are part of the legacy (`Compat32`) email API. There is no need to directly use these with the new API, since the parsing and formatting they provide is done automatically by the header parsing machinery of the new API.

email.utils.quote(*str*)

Return a new string with backslashes in *str* replaced by two backslashes, and double quotes replaced by backslash-double quote.

email.utils.unquote(*str*)

Return a new string which is an *unquoted* version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

email.utils.parseaddr(*address*)

Parse address – which should be the value of some address-containing field such as *To* or *Cc* – into its constituent *realname* and *email address* parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of `('', '')` is returned.

email.utils.formataddr(*pair*, *charset='utf-8'*)

The inverse of **`parseaddr()`**, this takes a 2-tuple of the form `(realname, email_address)` and returns the string value suitable for a *To* or *Cc* header. If the first element of *pair* is false, then the second element is returned unmodified.

Optional *charset* is the character set that will be used in the **RFC 2047** [https://datatracker.ietf.org/doc/html/rfc2047.html] encoding of the `realname` if the `realname` contains non-ASCII characters. Can be an instance of **`str`** or a **`Charset`**. Defaults to `utf-8`.

Changed in version 3.3: Added the *charset* option.

email.utils.getaddresses(*fieldvalues*)

This method returns a list of 2-tuples of the form returned by `parseaddr()`. *fieldvalues* is a sequence of header field values as might be returned by **`Message.get_all`**. Here's a simple example that gets all the recipients of a message:

```
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_to
```

email.utils.parsedate(*date*)

Attempts to parse a date according to the rules in **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html]. however, some mailers don't follow that format as specified, so **`parsedate()`** tries to guess correctly in such cases. *date* is a string containing an **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html] date, such as `"Mon, 20 Nov 1995 19:12:08 -0500"`. If it succeeds in parsing the date, **`parsedate()`** returns a 9-tuple that can be passed directly to **`time.mktime()`**; otherwise `None` will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.parsedate_tz(*date*)

Performs the same function as **`parsedate()`**, but returns either `None` or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to **`time.mktime()`**, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time) 1. If the input string has no timezone, the last element of the tuple returned is `0`, which represents UTC. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.parsedate_to_datetime(*date*)

The inverse of **`format_datetime()`**. Performs the same

function as **parsedate()**, but on success returns a **datetime**; otherwise `ValueError` is raised if *date* contains an invalid value such as an hour greater than 23 or a timezone offset not between -24 and 24 hours. If the input date has a timezone of `-0000`, the `datetime` will be a naive `datetime`, and if the date is conforming to the RFCs it will represent a time in UTC but with no indication of the actual source timezone of the message the date comes from. If the input date has any other valid timezone offset, the `datetime` will be an aware `datetime` with the corresponding a **timezone tzinfo**.

New in version 3.3.

email.utils.mktime_tz(*tuple*)

Turn a 10-tuple as returned by **parsedate_tz()** into a UTC timestamp (seconds since the Epoch). If the timezone item in the tuple is `None`, assume local time.

email.utils.formatdate(*timeval=None*, *localtime=False*, *usegmt=False*)

Returns a date string as per **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html], e.g.:

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional *timeval* if given is a floating point time value as accepted by **time.gmtime()** and **time.localtime()**, otherwise the current time is used.

Optional *localtime* is a flag that when `True`, interprets *timeval*, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is `False` meaning UTC is used.

Optional *usegmt* is a flag that when `True`, outputs a date string with the timezone as an ascii string `GMT`, rather than a numeric `-0000`. This is needed for some protocols (such as HTTP). This only applies when *localtime* is `False`. The

default is `False`.

email.utils.format_datetime(*dt*, *usegmt*=*False*)

Like `formatdate`, but the input is a **`datetime`** instance. If it is a naive datetime, it is assumed to be "UTC with no information about the source timezone", and the conventional `-0000` is used for the timezone. If it is an aware `datetime`, then the numeric timezone offset is used. If it is an aware timezone with offset zero, then *usegmt* may be set to `True`, in which case the string `GMT` is used instead of the numeric timezone offset. This provides a way to generate standards conformant HTTP date headers.

New in version 3.3.

email.utils.decode_rfc2231(*s*)

Decode the string *s* according to **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html].

email.utils.encode_rfc2231(*s*, *charset*=*None*, *language*=*None*)

Encode the string *s* according to **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html]. Optional *charset* and *language*, if given is the character set name and language name to use. If neither is given, *s* is returned as-is. If *charset* is given but *language* is not, the string is encoded using the empty string for *language*.

email.utils.collapse_rfc2231_value(*value*, *errors*=*'replace'*, *fallback_charset*=*'us-ascii'*)

When a header parameter is encoded in **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html] format, **`Message.get_param`** may return a 3-tuple containing the character set, language, and value. **`collapse_rfc2231_value()`** turns this into a unicode string. Optional *errors* is passed to the *errors* argument of **`str`**'s **`encode()`** method; it defaults to `'replace'`. Optional *fallback_charset* specifies the character set to use if the one in the **RFC 2231** [https://datatracker.ietf.org/doc/html/

rfc2231.html] header is not known by Python; it defaults to `'us-ascii'`.

For convenience, if the *value* passed to **`collapse_rfc2231_value()`** is not a tuple, it should be a string and it is returned unquoted.

email.utils.decode_params(*params*)

Decode parameters list according to **RFC 2231** [https://datatracker.ietf.org/doc/html/rfc2231.html]. *params* is a sequence of 2-tuples containing elements of the form `(content-type, string-value)`.

Footnotes

1

Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html].

`email.iterators`: Iterators

Source code: Lib/email/iterators.py [https://github.com/python/cpython/tree/3.11/Lib/email/iterators.py]

Iterating over a message object tree is fairly easy with the `Message.walk` method. The `email.iterators` module provides some useful higher level iterations over message object trees.

email.iterators.body_line_iterator(*msg*, *decode*=*False*)

> This iterates over all the payloads in all the subparts of *msg*, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn't a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using `readline()`, skipping over all the intervening headers.
>
> Optional *decode* is passed through to `Message.get_payload`.

email.iterators.typed_subpart_iterator(*msg*, *maintype*='*text*', *subtype*=*None*)

> This iterates over all the subparts of *msg*, returning only those subparts that match the MIME type specified by *maintype* and *subtype*.
>
> Note that *subtype* is optional; if omitted, then subpart MIME type matching is done only with the main type. *maintype* is optional too; it defaults to *text*.
>
> Thus, by default `typed_subpart_iterator()` returns each subpart that has a MIME type of *text*/*.

The following function has been added as a useful debugging tool. It should *not* be considered part of the supported public interface for the package.

email.iterators._structure(*msg*, *fp*=*None*, *level*=*0*, *include_default*=*False*)

Prints an indented representation of the content types of the message object structure. For example:

```
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
    text/plain
    text/plain
    multipart/digest
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
    text/plain
```

Optional *fp* is a file-like object to print the output to. It must be suitable for Python's `print()` function. *level* is used internally. *include_default*, if true, prints the default type as well.

`json` — JSON encoder and decoder

Source code: Lib/json/__init__.py [https://github.com/python/cpython/tree/3.11/Lib/json/__init__.py]

JSON (JavaScript Object Notation) [https://json.org], specified by **RFC 7159** [https://datatracker.ietf.org/doc/html/rfc7159.html] (which obsoletes **RFC 4627** [https://datatracker.ietf.org/doc/html/rfc4627.html]) and by ECMA-404 [https://www.ecma-international.org/publications-and-standards/standards/ecma-404/], is a lightweight data interchange format inspired by JavaScript [https://en.wikipedia.org/wiki/JavaScript] object literal syntax (although it is not a strict subset of JavaScript 1).

Warning

Be cautious when parsing JSON data from untrusted sources. A malicious JSON string may cause the decoder to consume considerable CPU and memory resources. Limiting the size of data to be parsed is recommended.

`json` exposes an API familiar to users of the standard library `marshal` and `pickle` modules.

Encoding basic Python object hierarchies:

```
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2)}])
'["foo", {"bar": ["baz", null, 1.0, 2]}]'
>>> print(json.dumps("\"foo\bar"))
"\"foo\bar"
>>> print(json.dumps('\u1234'))
"\u1234"
>>> print(json.dumps('\\'))
```

```
"\\"
>>> print(json.dumps({"c": 0, "b": 0, "a": 0}, sort_keys
{"a": 0, "b": 0, "c": 0}
>>> from io import StringIO
>>> io = StringIO()
>>> json.dump(['streaming API'], io)
>>> io.getvalue()
'["streaming API"]'
```

Compact encoding:

```
>>> import json
>>> json.dumps([1, 2, 3, {'4': 5, '6': 7}], separators=(
'[1,2,3,{"4":5,"6":7}]'
```

Pretty printing:

```
>>> import json
>>> print(json.dumps({'4': 5, '6': 7}, sort_keys=True, i
{
    "4": 5,
    "6": 7
}
```

Decoding JSON:

```
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]')
['foo', {'bar': ['baz', None, 1.0, 2]}]
>>> json.loads('"\\"foo\\bar"')
'"foo\x08ar'
>>> from io import StringIO
>>> io = StringIO('["streaming API"]')
>>> json.load(io)
['streaming API']
```

Specializing JSON object decoding:

```
>>> import json
>>> def as_complex(dct):
```

```
...     if '__complex__' in dct:
...         return complex(dct['real'], dct['imag'])
...     return dct
...
>>> json.loads('{"__complex__": true, "real": 1, "imag":
...     object_hook=as_complex)
(1+2j)
>>> import decimal
>>> json.loads('1.1', parse_float=decimal.Decimal)
Decimal('1.1')
```

Extending **`JSONEncoder`**:

```
>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...     def default(self, obj):
...         if isinstance(obj, complex):
...             return [obj.real, obj.imag]
...         # Let the base class default method raise th
...         return json.JSONEncoder.default(self, obj)
...
>>> json.dumps(2 + 1j, cls=ComplexEncoder)
'[2.0, 1.0]'
>>> ComplexEncoder().encode(2 + 1j)
'[2.0, 1.0]'
>>> list(ComplexEncoder().iterencode(2 + 1j))
['[2.0', ', 1.0', ']']
```

Using **`json.tool`** from the shell to validate and pretty-print:

```
$ echo '{"json":"obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes: line
```

See Command Line Interface for detailed documentation.

Note

JSON is a subset of YAML [https://yaml.org/] 1.2. The JSON produced by this module's default settings (in particular, the default *separators* value) is also a subset of YAML 1.0 and 1.1. This module can thus also be used as a YAML serializer.

Note

This module's encoders and decoders preserve input and output order by default. Order is only lost if the underlying containers are unordered.

Basic Usage

json.dump(*obj*, *fp*, ***, *skipkeys=False*, *ensure_ascii=True*, *check_circular=True*, *allow_nan=True*, *cls=None*, *indent=None*, *separators=None*, *default=None*, *sort_keys=False*, ***kw*)

Serialize *obj* as a JSON formatted stream to *fp* (a `.write()`-supporting file-like object) using this conversion table.

If *skipkeys* is true (default: `False`), then dict keys that are not of a basic type (**`str`**, **`int`**, **`float`**, **`bool`**, `None`) will be skipped instead of raising a **`TypeError`**.

The **`json`** module always produces **`str`** objects, not **`bytes`** objects. Therefore, `fp.write()` must support **`str`** input.

If *ensure_ascii* is true (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If *ensure_ascii* is false, these characters will be output as-is.

If *check_circular* is false (default: `True`), then the circular reference check for container types will be skipped and a circular reference will result in a **`RecursionError`** (or worse).

If *allow_nan* is false (default: `True`), then it will be a

ValueError to serialize out of range **float** values (`nan`, `inf`, `-inf`) in strict compliance of the JSON specification. If *allow_nan* is true, their JavaScript equivalents (`NaN`, `Infinity`, `-Infinity`) will be used.

If *indent* is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or `""` will only insert newlines. `None` (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If *indent* is a string (such as `"\t"`), that string is used to indent each level.

Changed in version 3.2: Allow strings for *indent* in addition to integers.

If specified, *separators* should be an `(item_separator, key_separator)` tuple. The default is `(', ', ': ')` if *indent* is `None` and `(',', ': ')` otherwise. To get the most compact JSON representation, you should specify `(',', ':')` to eliminate whitespace.

Changed in version 3.4: Use `(',', ': ')` as default if *indent* is not `None`.

If specified, *default* should be a function that gets called for objects that can't otherwise be serialized. It should return a JSON encodable version of the object or raise a **TypeError**. If not specified, **TypeError** is raised.

If *sort_keys* is true (default: `False`), then the output of dictionaries will be sorted by key.

To use a custom **JSONEncoder** subclass (e.g. one that overrides the **default()** method to serialize additional types), specify it with the *cls* kwarg; otherwise **JSONEncoder** is used.

Changed in version 3.6: All optional parameters are now keyword-only.

Note

Unlike **pickle** and **marshal**, JSON is not a framed protocol, so trying to serialize multiple objects with repeated calls to **dump()** using the same *fp* will result in an invalid JSON file.

json.dumps(*obj*, *, *skipkeys*=*False*, *ensure_ascii*=*True*, *check_circular*=*True*, *allow_nan*=*True*, *cls*=*None*, *indent*=*None*, *separators*=*None*, *default*=*None*, *sort_keys*=*False*, **kw*)

Serialize *obj* to a JSON formatted **str** using this conversion table. The arguments have the same meaning as in **dump()**.

Note

Keys in key/value pairs of JSON are always of the type **str**. When a dictionary is converted into JSON, all the keys of the dictionary are coerced to strings. As a result of this, if a dictionary is converted into JSON and then back into a dictionary, the dictionary may not equal the original one. That is, `loads(dumps(x)) != x` if x has non-string keys.

json.load(*fp*, *, *cls*=*None*, *object_hook*=*None*, *parse_float*=*None*, *parse_int*=*None*, *parse_constant*=*None*, *object_pairs_hook*=*None*, **kw*)

Deserialize *fp* (a `.read()`-supporting text file or binary file containing a JSON document) to a Python object using this conversion table.

object_hook is an optional function that will be called with the result of any object literal decoded (a **dict**). The return value of *object_hook* will be used instead of the **dict**. This feature can be used to implement custom decoders (e.g. JSON-RPC [https://www.jsonrpc.org] class hinting).

object_pairs_hook is an optional function that will be called

with the result of any object literal decoded with an ordered list of pairs. The return value of *object_pairs_hook* will be used instead of the **dict**. This feature can be used to implement custom decoders. If *object_hook* is also defined, the *object_pairs_hook* takes priority.

Changed in version 3.1: Added support for *object_pairs_hook*.

parse_float, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. **decimal.Decimal**).

parse_int, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. **float**).

Changed in version 3.11: The default *parse_int* of **int()** now limits the maximum length of the integer string via the interpreter's integer string conversion length limitation to help avoid denial of service attacks.

parse_constant, if specified, will be called with one of the following strings: `'-Infinity'`, `'Infinity'`, `'NaN'`. This can be used to raise an exception if invalid JSON numbers are encountered.

Changed in version 3.1: parse_constant doesn't get called on 'null', 'true', 'false' anymore.

To use a custom **JSONDecoder** subclass, specify it with the `cls` kwarg; otherwise **JSONDecoder** is used. Additional keyword arguments will be passed to the constructor of the class.

If the data being deserialized is not a valid JSON document, a **JSONDecodeError** will be raised.

Changed in version 3.6: All optional parameters are now keyword-only.

Changed in version 3.6: *fp* can now be a binary file. The input encoding should be UTF-8, UTF-16 or UTF-32.

json.loads(*s*, ***, *cls=None*, *object_hook=None*, *parse_float=None*, *parse_int=None*, *parse_constant=None*, *object_pairs_hook=None*, ***kw*)

Deserialize *s* (a `str`, `bytes` or `bytearray` instance containing a JSON document) to a Python object using this conversion table.

The other arguments have the same meaning as in `load()`.

If the data being deserialized is not a valid JSON document, a `JSONDecodeError` will be raised.

Changed in version 3.6: *s* can now be of type `bytes` or `bytearray`. The input encoding should be UTF-8, UTF-16 or UTF-32.

Changed in version 3.9: The keyword argument *encoding* has been removed.

Encoders and Decoders

class json.JSONDecoder(***, *object_hook=None*, *parse_float=None*, *parse_int=None*, *parse_constant=None*, *strict=True*, *object_pairs_hook=None*)

Simple JSON decoder.

Performs the following translations in decoding by default:

JSON	Python
object	dict
array	list
string	str
number (int)	int
number (real)	float
true	True
false	False
null	None

It also understands `NaN`, `Infinity`, and `-Infinity` as their corresponding `float` values, which is outside the JSON spec.

object_hook, if specified, will be called with the result of every JSON object decoded and its return value will be used in place of the given **`dict`**. This can be used to provide custom deserializations (e.g. to support JSON-RPC [https://www.jsonrpc.org] class hinting).

object_pairs_hook, if specified will be called with the result of every JSON object decoded with an ordered list of pairs. The return value of *object_pairs_hook* will be used instead of the **`dict`**. This feature can be used to implement custom decoders. If *object_hook* is also defined, the *object_pairs_hook* takes priority.

Changed in version 3.1: Added support for *object_pairs_hook*.

parse_float, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. **`decimal.Decimal`**).

parse_int, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. **`float`**).

parse_constant, if specified, will be called with one of the following strings: `'-Infinity'`, `'Infinity'`, `'NaN'`. This can be used to raise an exception if invalid JSON numbers are encountered.

If *strict* is false (`True` is the default), then control characters will be allowed inside strings. Control characters in this context are those with character codes in the 0–31 range, including `'\t'` (tab), `'\n'`, `'\r'` and `'\0'`.

If the data being deserialized is not a valid JSON document, a

JSONDecodeError will be raised.

Changed in version 3.6: All parameters are now keyword-only.

decode(*s*)

Return the Python representation of *s* (a **str** instance containing a JSON document).

JSONDecodeError will be raised if the given JSON document is not valid.

raw_decode(*s*)

Decode a JSON document from *s* (a **str** beginning with a JSON document) and return a 2-tuple of the Python representation and the index in *s* where the document ended.

This can be used to decode a JSON document from a string that may have extraneous data at the end.

class json.JSONEncoder(*, *skipkeys=False*, *ensure_ascii=True*, *check_circular=True*, *allow_nan=True*, *sort_keys=False*, *indent=None*, *separators=None*, *default=None*)

Extensible JSON encoder for Python data structures.

Supports the following objects and types by default:

Python	JSON
dict	object
list, tuple	array
str	string
int, float, int- & float-derived Enums	number
True	true
False	false
None	null

Changed in version 3.4: Added support for int- and float-derived Enum classes.

To extend this to recognize other objects, subclass and

implement a **`default()`** method with another method that returns a serializable object for `o` if possible, otherwise it should call the superclass implementation (to raise **`TypeError`**).

If *skipkeys* is false (the default), a **`TypeError`** will be raised when trying to encode keys that are not **`str`**, **`int`**, **`float`** or `None`. If *skipkeys* is true, such items are simply skipped.

If *ensure_ascii* is true (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If *ensure_ascii* is false, these characters will be output as-is.

If *check_circular* is true (the default), then lists, dicts, and custom encoded objects will be checked for circular references during encoding to prevent an infinite recursion (which would cause a **`RecursionError`**). Otherwise, no such check takes place.

If *allow_nan* is true (the default), then `NaN`, `Infinity`, and `-Infinity` will be encoded as such. This behavior is not JSON specification compliant, but is consistent with most JavaScript based encoders and decoders. Otherwise, it will be a **`ValueError`** to encode such floats.

If *sort_keys* is true (default: `False`), then the output of dictionaries will be sorted by key; this is useful for regression tests to ensure that JSON serializations can be compared on a day-to-day basis.

If *indent* is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or `""` will only insert newlines. `None` (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If *indent* is a string (such as `"\t"`), that string is used to indent each level.

Changed in version 3.2: Allow strings for *indent* in addition to integers.

If specified, *separators* should be an `(item_separator, key_separator)` tuple. The default is `(', ', ': ')` if *indent* is `None` and `(',', ': ')` otherwise. To get the most compact JSON representation, you should specify `(',', ':')` to eliminate whitespace.

Changed in version 3.4: Use `(',', ': ')` as default if *indent* is not `None`.

If specified, *default* should be a function that gets called for objects that can't otherwise be serialized. It should return a JSON encodable version of the object or raise a **`TypeError`**. If not specified, **`TypeError`** is raised.

Changed in version 3.6: All parameters are now keyword-only.

default(*o*)

Implement this method in a subclass such that it returns a serializable object for *o*, or calls the base implementation (to raise a **`TypeError`**).

For example, to support arbitrary iterators, you could implement **`default()`** like this:

```
def default(self, o):
    try:
        iterable = iter(o)
    except TypeError:
        pass
    else:
        return list(iterable)
    # Let the base class default method raise th
    return json.JSONEncoder.default(self, o)
```

encode(*o*)

Return a JSON string representation of a Python data structure, *o*. For example:

```
>>> json.JSONEncoder().encode({"foo": ["bar", '
'{"foo": ["bar", "baz"]}'
```

iterencode(*o*)

Encode the given object, *o*, and yield each string representation as available. For example:

```
for chunk in json.JSONEncoder().iterencode(bigo
    mysocket.write(chunk)
```

Exceptions

exception json.JSONDecodeError(*msg*, *doc*, *pos*)

Subclass of **`ValueError`** with the following additional attributes:

msg

The unformatted error message.

doc

The JSON document being parsed.

pos

The start index of *doc* where parsing failed.

lineno

The line corresponding to *pos*.

colno

The column corresponding to *pos*.

New in version 3.5.

Standard Compliance and Interoperability

The JSON format is specified by **RFC 7159** [https://datatracker.ietf.org/doc/html/rfc7159.html] and by ECMA-404 [https://www.ecma-international.org/publications-and-standards/standards/ecma-404/]. This section details this module's level of compliance with the RFC. For

simplicity, `JSONEncoder` and `JSONDecoder` subclasses, and parameters other than those explicitly mentioned, are not considered.

This module does not comply with the RFC in a strict fashion, implementing some extensions that are valid JavaScript but not valid JSON. In particular:

- Infinite and NaN number values are accepted and output;
- Repeated names within an object are accepted, and only the value of the last name-value pair is used.

Since the RFC permits RFC-compliant parsers to accept input texts that are not RFC-compliant, this module's deserializer is technically RFC-compliant under default settings.

Character Encodings

The RFC requires that JSON be represented using either UTF-8, UTF-16, or UTF-32, with UTF-8 being the recommended default for maximum interoperability.

As permitted, though not required, by the RFC, this module's serializer sets *ensure_ascii*=*True* by default, thus escaping the output so that the resulting strings only contain ASCII characters.

Other than the *ensure_ascii* parameter, this module is defined strictly in terms of conversion between Python objects and `Unicode strings`, and thus does not otherwise directly address the issue of character encodings.

The RFC prohibits adding a byte order mark (BOM) to the start of a JSON text, and this module's serializer does not add a BOM to its output. The RFC permits, but does not require, JSON deserializers to ignore an initial BOM in their input. This module's deserializer raises a `ValueError` when an initial BOM is present.

The RFC does not explicitly forbid JSON strings which contain byte sequences that don't correspond to valid Unicode characters (e.g. unpaired UTF-16 surrogates), but it does note that they may cause interoperability problems. By default, this module accepts and

outputs (when present in the original `str`) code points for such sequences.

Infinite and NaN Number Values

The RFC does not permit the representation of infinite or NaN number values. Despite that, by default, this module accepts and outputs `Infinity`, `-Infinity`, and `NaN` as if they were valid JSON number literal values:

```
>>> # Neither of these calls raises an exception, but th
>>> json.dumps(float('-inf'))
'-Infinity'
>>> json.dumps(float('nan'))
'NaN'
>>> # Same when deserializing
>>> json.loads('-Infinity')
-inf
>>> json.loads('NaN')
nan
```

In the serializer, the *allow_nan* parameter can be used to alter this behavior. In the deserializer, the *parse_constant* parameter can be used to alter this behavior.

Repeated Names Within an Object

The RFC specifies that the names within a JSON object should be unique, but does not mandate how repeated names in JSON objects should be handled. By default, this module does not raise an exception; instead, it ignores all but the last name-value pair for a given name:

```
>>> weird_json = '{"x": 1, "x": 2, "x": 3}'
>>> json.loads(weird_json)
{'x': 3}
```

The *object_pairs_hook* parameter can be used to alter this behavior.

Top-level Non-Object, Non-Array Values

The old version of JSON specified by the obsolete **RFC 4627** [https://datatracker.ietf.org/doc/html/rfc4627.html] required that the top-level value of a JSON text must be either a JSON object or array (Python `dict` or `list`), and could not be a JSON null, boolean, number, or string value. **RFC 7159** [https://datatracker.ietf.org/doc/html/rfc7159.html] removed that restriction, and this module does not and has never implemented that restriction in either its serializer or its deserializer.

Regardless, for maximum interoperability, you may wish to voluntarily adhere to the restriction yourself.

Implementation Limitations

Some JSON deserializer implementations may set limits on:

- the size of accepted JSON texts
- the maximum level of nesting of JSON objects and arrays
- the range and precision of JSON numbers
- the content and maximum length of JSON strings

This module does not impose any such limits beyond those of the relevant Python datatypes themselves or the Python interpreter itself.

When serializing to JSON, beware any such limitations in applications that may consume your JSON. In particular, it is common for JSON numbers to be deserialized into IEEE 754 double precision numbers and thus subject to that representation's range and precision limitations. This is especially relevant when serializing Python `int` values of extremely large magnitude, or when serializing instances of "exotic" numerical types such as `decimal.Decimal`.

Command Line Interface

Source code: Lib/json/tool.py [https://github.com/python/cpython/tree/3.11/Lib/json/tool.py]

The **json.tool** module provides a simple command line interface to validate and pretty-print JSON objects.

If the optional `infile` and `outfile` arguments are not specified, **sys.stdin** and **sys.stdout** will be used respectively:

```
$ echo '{"json": "obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes: line
```

Changed in version 3.5: The output is now in the same order as the input. Use the **--sort-keys** option to sort the output of dictionaries alphabetically by key.

Command line options

infile

The JSON file to be validated or pretty-printed:

```
$ python -m json.tool mp_films.json
[
    {
        "title": "And Now for Something Completely
        "year": 1971
    },
    {
        "title": "Monty Python and the Holy Grail",
        "year": 1975
    }
]
```

If *infile* is not specified, read from **sys.stdin**.

outfile

Write the output of the *infile* to the given *outfile*. Otherwise, write it to **sys.stdout**.

--sort-keys

Sort the output of dictionaries alphabetically by key.

New in version 3.5.

--no-ensure-ascii

Disable escaping of non-ascii characters, see `json.dumps()` for more information.

New in version 3.9.

--json-lines

Parse every input line as separate JSON object.

New in version 3.8.

--indent, --tab, --no-indent, --compact

Mutually exclusive options for whitespace control.

New in version 3.9.

-h, --help

Show the help message.

Footnotes

1

As noted in the errata for RFC 7159 [https://www.rfc-editor.org/errata_search.php?rfc=7159], JSON permits literal U+2028 (LINE SEPARATOR) and U+2029 (PARAGRAPH SEPARATOR) characters in strings, whereas JavaScript (as of ECMAScript Edition 5.1) does not.

`mailbox` — Manipulate mailboxes in various formats

Source code: Lib/mailbox.py [https://github.com/python/cpython/tree/3.11/Lib/mailbox.py]

This module defines two classes, `Mailbox` and `Message`, for accessing and manipulating on-disk mailboxes and the messages they contain. `Mailbox` offers a dictionary-like mapping from keys to messages. `Message` extends the `email.message` module's `Message` class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

See also

Module `email`
Represent and manipulate messages.

`Mailbox` objects

class mailbox.Mailbox

A mailbox, which may be inspected and modified.

The `Mailbox` class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from `Mailbox` and your code should instantiate a particular subclass.

The `Mailbox` interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the `Mailbox` instance with which they will be used and are only meaningful to that `Mailbox` instance. A key continues to identify a message even if the corresponding message is

modified, such as by replacing it with another message.

Messages may be added to a **`Mailbox`** instance using the set-like method **`add()`** and removed using a `del` statement or the set-like methods **`remove()`** and **`discard()`**.

`Mailbox` interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a **`Message`** instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a **`Mailbox`** instance, the provided message representation's contents are copied. In neither case is a reference to the message representation kept by the **`Mailbox`** instance.

The default **`Mailbox`** iterator iterates over message representations, not keys as the default dictionary iterator does. Moreover, modification of a mailbox during iteration is safe and well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a **`KeyError`** exception if the corresponding message is subsequently removed.

Warning

Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is Maildir; try to avoid using single-file formats such as mbox for concurrent writing. If you're modifying a mailbox, you *must* lock it by calling the **`lock()`** and **`unlock()`** methods *before* reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

`Mailbox` instances have the following methods:

add(*message*)

Add *message* to the mailbox and return the key that has been assigned to it.

Parameter *message* may be a `Message` instance, an `email.message.Message` instance, a string, a byte string, or a file-like object (which should be open in binary mode). If *message* is an instance of the appropriate format-specific `Message` subclass (e.g., if it's an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

Changed in version 3.2: Support for binary input was added.

remove(*key*)
__delitem__(*key*)
discard(*key*)

Delete the message corresponding to *key* from the mailbox.

If no such message exists, a `KeyError` exception is raised if the method was called as `remove()` or `__delitem__()` but no exception is raised if the method was called as `discard()`. The behavior of `discard()` may be preferred if the underlying mailbox format supports concurrent modification by other processes.

__setitem__(*key*, *message*)

Replace the message corresponding to *key* with *message*. Raise a `KeyError` exception if no message already corresponds to *key*.

As with `add()`, parameter *message* may be a `Message` instance, an `email.message.Message` instance, a string, a byte string, or a file-like object (which should

be open in binary mode). If *message* is an instance of the appropriate format-specific **Message** subclass (e.g., if it's an **mboxMessage** instance and this is an **mbox** instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to *key* is left unchanged.

iterkeys()
keys()

Return an iterator over all keys if called as **iterkeys()** or return a list of keys if called as **keys()**.

itervalues()
iter()
values()

Return an iterator over representations of all messages if called as **itervalues()** or **__iter__()** or return a list of such representations if called as **values()**. The messages are represented as instances of the appropriate format-specific **Message** subclass unless a custom message factory was specified when the **Mailbox** instance was initialized.

Note

The behavior of **__iter__()** is unlike that of dictionaries, which iterate over keys.

iteritems()
items()

Return an iterator over (*key*, *message*) pairs, where *key* is a key and *message* is a message representation, if called as **iteritems()** or return a list of such pairs if called as **items()**. The messages are represented as

instances of the appropriate format-specific **Message** subclass unless a custom message factory was specified when the **Mailbox** instance was initialized.

get(*key*, *default*=*None*)

getitem(*key*)

Return a representation of the message corresponding to *key*. If no such message exists, *default* is returned if the method was called as **get()** and a **KeyError** exception is raised if the method was called as **__getitem__()**. The message is represented as an instance of the appropriate format-specific **Message** subclass unless a custom message factory was specified when the **Mailbox** instance was initialized.

get_message(*key*)

Return a representation of the message corresponding to *key* as an instance of the appropriate format-specific **Message** subclass, or raise a **KeyError** exception if no such message exists.

get_bytes(*key*)

Return a byte representation of the message corresponding to *key*, or raise a **KeyError** exception if no such message exists.

New in version 3.2.

get_string(*key*)

Return a string representation of the message corresponding to *key*, or raise a **KeyError** exception if no such message exists. The message is processed through **email.message.Message** to convert it to a 7bit clean representation.

get_file(*key*)

Return a file-like representation of the message

corresponding to *key*, or raise a **KeyError** exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

Changed in version 3.2: The file object really is a binary file; previously it was incorrectly returned in text mode. Also, the file-like object now supports the context management protocol: you can use a **with** statement to automatically close it.

Note

Unlike other representations of messages, file-like representations are not necessarily independent of the **Mailbox** instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

contains(*key*)

Return `True` if *key* corresponds to a message, `False` otherwise.

len()

Return a count of messages in the mailbox.

clear()

Delete all messages from the mailbox.

pop(*key*, *default*=*None*)

Return a representation of the message corresponding to *key* and delete the message. If no such message exists, return *default*. The message is represented as an instance of the appropriate format-specific **Message** subclass unless a custom message factory was specified when the **Mailbox** instance was initialized.

popitem()

Return an arbitrary (*key*, *message*) pair, where *key* is a key and *message* is a message representation, and delete the corresponding message. If the mailbox is empty, raise a **KeyError** exception. The message is represented as an instance of the appropriate format-specific **Message** subclass unless a custom message factory was specified when the **Mailbox** instance was initialized.

update(*arg*)

Parameter *arg* should be a *key*-to-*message* mapping or an iterable of (*key*, *message*) pairs. Updates the mailbox so that, for each given *key* and *message*, the message corresponding to *key* is set to *message* as if by using **__setitem__()**. As with **__setitem__()**, each *key* must already correspond to a message in the mailbox or else a **KeyError** exception will be raised, so in general it is incorrect for *arg* to be a **Mailbox** instance.

Note

Unlike with dictionaries, keyword arguments are not supported.

flush()

Write any pending changes to the filesystem. For some **Mailbox** subclasses, changes are always written immediately and **flush()** does nothing, but you should still make a habit of calling this method.

lock()

Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An **ExternalClashError** is raised if the lock is not available. The particular locking mechanisms used

depend upon the mailbox format. You should *always* lock the mailbox before making any modifications to its contents.

unlock()

Release the lock on the mailbox, if any.

close()

Flush the mailbox, unlock it if necessary, and close any open files. For some **Mailbox** subclasses, this method does nothing.

Maildir

class mailbox.Maildir(*dirname*, *factory*=*None*, *create*=*True*)

A subclass of **Mailbox** for mailboxes in Maildir format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, **MaildirMessage** is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

If *create* is `True` and the *dirname* path exists, it will be treated as an existing maildir without attempting to verify its directory layout.

It is for historical reasons that *dirname* is named as such rather than *path*.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs. Messages in a Maildir mailbox are stored in separate files within a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely: `tmp`,

`new`, and `cur`. Messages are created momentarily in the `tmp` subdirectory and then moved to the `new` subdirectory to finalize delivery. A mail user agent may subsequently move the message to the `cur` subdirectory and store information about the state of the message in a special “info” section appended to its file name.

Folders of the style introduced by the Courier mail transfer agent are also supported. Any subdirectory of the main mailbox is considered a folder if `'.'` is the first character in its name. Folder names are represented by **`Maildir`** without the leading `'.'`. Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using `'.'` to delimit levels, e.g., “Archived.2005.07”.

Note

The Maildir specification requires the use of a colon (`':'`) in certain message file names. However, some operating systems do not permit this character in file names, If you wish to use a Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point (`'!'`) is a popular choice. For example:

```
import mailbox
mailbox.Maildir.colon = '!'
```

The **`colon`** attribute may also be set on a per-instance basis.

`Maildir` instances have all of the methods of **`Mailbox`** in addition to the following:

list_folders()

Return a list of the names of all folders.

get_folder(*folder*)

Return a **Maildir** instance representing the folder whose name is *folder*. A **NoSuchMailboxError** exception is raised if the folder does not exist.

add_folder(*folder*)

Create a folder whose name is *folder* and return a **Maildir** instance representing it.

remove_folder(*folder*)

Delete the folder whose name is *folder*. If the folder contains any messages, a **NotEmptyError** exception will be raised and the folder will not be deleted.

clean()

Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

Some **Mailbox** methods implemented by **Maildir** deserve special remarks:

add(*message*)
setitem(*key*, *message*)
update(*arg*)

Warning

These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.

flush()

All changes to Maildir mailboxes are immediately applied, so this method does nothing.

lock()
unlock()

Maildir mailboxes do not support (or require) locking, so these methods do nothing.

close()

`Maildir` instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

get_file(*key*)

Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

Notes on Maildir by its inventor. Includes an updated name-creation scheme and details on “info” semantics.

mbox

class mailbox.mbox(*path*, *factory*=*None*, *create*=*True*)

A subclass of `Mailbox` for mailboxes in mbox format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, `mboxMessage` is used as the default message

representation. If *create* is `True`, the mailbox is created if it does not exist.

The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are “From “.

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, **`mbox`** implements the original format, which is sometimes referred to as *mboxo*. This means that the *Content-Length* header, if present, is ignored and that any occurrences of “From ” at the beginning of a line in a message body are transformed to “ >From ” when storing the message, although occurrences of “ >From ” are not transformed to “From ” when reading the message.

Some **`Mailbox`** methods implemented by **`mbox`** deserve special remarks:

get_file(*key*)

Using the file after calling **`flush()`** or **`close()`** on the **`mbox`** instance may yield unpredictable results or raise an exception.

lock()

unlock()

Three locking mechanisms are used—dot locking and, if available, the **`flock()`** and **`lockf()`** system calls.

A history of mbox variations.

MH

class mailbox.MH(*path*, *factory*=*None*, *create*=*True*)

A subclass of **Mailbox** for mailboxes in MH format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, **MHMessage** is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH Message Handling System, a mail user agent. Each message in an MH mailbox resides in its own file. An MH mailbox may contain other MH mailboxes (called *folders*) in addition to messages. Folders may be nested indefinitely. MH mailboxes also support *sequences*, which are named lists used to logically group messages without moving them to sub-folders. Sequences are defined in a file called `.mh_sequences` in each folder.

The **MH** class manipulates MH mailboxes, but it does not attempt to emulate all of **mh**'s behaviors. In particular, it does not modify and is not affected by the `context` or `.mh_profile` files that are used by **mh** to store its state and configuration.

MH instances have all of the methods of **Mailbox** in addition to the following:

list_folders()

Return a list of the names of all folders.

get_folder(*folder*)

Return an `MH` instance representing the folder whose name is *folder*. A `NoSuchMailboxError` exception is raised if the folder does not exist.

add_folder(*folder*)

Create a folder whose name is *folder* and return an `MH` instance representing it.

remove_folder(*folder*)

Delete the folder whose name is *folder*. If the folder contains any messages, a `NotEmptyError` exception will be raised and the folder will not be deleted.

get_sequences()

Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

set_sequences(*sequences*)

Re-define the sequences that exist in the mailbox based upon *sequences*, a dictionary of names mapped to key lists, like returned by `get_sequences()`.

pack()

Rename messages in the mailbox as necessary to eliminate gaps in numbering. Entries in the sequences list are updated correspondingly.

Note

Already-issued keys are invalidated by this operation and should not be subsequently used.

Some **Mailbox** methods implemented by **MH** deserve special remarks:

remove(*key*)
delitem(*key*)
discard(*key*)

These methods immediately delete the message. The MH convention of marking a message for deletion by prepending a comma to its name is not used.

lock()
unlock()

Three locking mechanisms are used—dot locking and, if available, the **flock()** and **lockf()** system calls. For MH mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

get_file(*key*)

Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

flush()

All changes to MH mailboxes are immediately applied, so this method does nothing.

close()

MH instances do not keep any open files, so this method is equivalent to **unlock()**.

: A GPL-licensed book on **mh** and **nmh**, with some information on the mailbox format.

Babyl

class mailbox.Babyl(*path*, *factory*=*None*, *create*=*True*)

A subclass of **Mailbox** for mailboxes in Babyl format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, **BabylMessage** is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

Babyl is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore (`'\037'`) and Control-L (`'\014'`). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore (`'\037'`) character.

Messages in a Babyl mailbox have two sets of headers, original headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a Babyl mailbox also has an accompanying list of *labels*, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

Babyl instances have all of the methods of **Mailbox** in addition to the following:

get_labels()

Return a list of the names of all user-defined labels used in the mailbox.

Note

The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

Some `Mailbox` methods implemented by `Babyl` deserve special remarks:

get_file(*key*)

In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into an `io.BytesIO` instance, which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

lock()

unlock()

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

The Rmail manual, with some information on Babyl

semantics.

MMDF

class mailbox.MMDF(*path*, *factory*=*None*, *create*=*True*)

A subclass of **Mailbox** for mailboxes in MMDF format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, **MMDFMessage** is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A (`'\001'`) characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are "From ", but additional occurrences of "From " are not transformed to ">From " when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.

Some **Mailbox** methods implemented by **MMDF** deserve special remarks:

get_file(*key*)

Using the file after calling **flush()** or **close()** on the **MMDF** instance may yield unpredictable results or raise an exception.

lock()

unlock()

Three locking mechanisms are used—dot locking and, if available, the **flock()** and **lockf()** system calls.

: A Wikipedia article describing the Multichannel Memorandum Distribution Facility.

`Message` objects

class mailbox.Message(*message=None*)

A subclass of the `email.message` module's `Message`. Subclasses of `mailbox.Message` add mailbox-format-specific state and behavior.

If *message* is omitted, the new instance is created in a default, empty state. If *message* is an `email.message.Message` instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if *message* is a `Message` instance. If *message* is a string, a byte string, or a file, it should contain an **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html]-compliant message, which is read and parsed. Files should be open in binary mode, but text mode files are accepted for backward compatibility.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that **Message** instances be used to represent messages retrieved using **Mailbox** instances. In some situations, the time and memory required to generate **Message** representations might not be acceptable. For such situations, **Mailbox** instances also offer string and file-like representations, and a custom message factory may be specified when a **Mailbox** instance is initialized.

MaildirMessage

class mailbox.MaildirMessage(*message*=*None*)

A message with Maildir-specific behaviors. Parameter *message* has the same meaning as with the **Message** constructor.

Typically, a mail user agent application moves all of the messages in the `new` subdirectory to the `cur` subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they've actually been read. Each message in `cur` has an "info" section added to its file name to store information about its state. (Some mail readers may also add an "info" section to messages in `new`.) The "info" section may take one of two forms: it may contain "2," followed by a list of standardized flags (e.g., "2,FR") or it may contain "1," followed by so-called experimental information. Standard flags for Maildir messages are as follows:

Flag	Meaning
D	Draft
F	Flagged
P	Passed
R	Replied to
S	Seen
T	Trashed

MaildirMessage instances offer the following methods:

get_subdir()

Return either "new" (if the message should be stored in the `new` subdirectory) or "cur" (if the message should

be stored in the `cur` subdirectory).

Note

A message is typically moved from `new` to `cur` after its mailbox has been accessed, whether or not the message is has been read. A message `msg` has been read if `"S" in msg.get_flags()` is `True`.

set_subdir(*subdir*)

Set the subdirectory the message should be stored in. Parameter *subdir* must be either “new” or “cur”.

get_flags()

Return a string specifying the flags that are currently set. If the message complies with the standard Maildir format, the result is the concatenation in alphabetical order of zero or one occurrence of each of `'D'`, `'F'`, `'P'`, `'R'`, `'S'`, and `'T'`. The empty string is returned if no flags are set or if “info” contains experimental semantics.

set_flags(*flags*)

Set the flags specified by *flags* and unset all others.

add_flag(*flag*)

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character. The current “info” is overwritten whether or not it contains experimental information rather than flags.

remove_flag(*flag*)

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character. If “info”

contains experimental information rather than flags, the current “info” is not modified.

get_date()

Return the delivery date of the message as a floating-point number representing seconds since the epoch.

set_date(*date*)

Set the delivery date of the message to *date*, a floating-point number representing seconds since the epoch.

get_info()

Return a string containing the “info” for a message. This is useful for accessing and modifying “info” that is experimental (i.e., not a list of flags).

set_info(*info*)

Set “info” to *info*, which should be a string.

When a `MaildirMessage` instance is created based upon an `mboxMessage` or `MMDFMessage` instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

Resulting state	`mboxMessage` or `MMDFMessage` state
`cur` subdirectory	O flag
F flag	F flag
R flag	A flag
S flag	R flag
T flag	D flag

When a `MaildirMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

Resulting state	`MHMessage` state
“cur” subdirectory	“unseen” sequence
“cur” subdirectory and S flag	no “unseen” sequence
F flag	“flagged” sequence
R flag	“replied” sequence

When a `MaildirMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

`BabylMessage` state	Resulting state
“unseen” label	No S flag
No “unseen” label	S flag
“forwarded” or “resent” label	P flag
No “forwarded” or “resent” label	No P flag
“answered” label	R flag
No “answered” label	No R flag

`mboxMessage`

class mailbox.mboxMessage(*message=None*)

A message with mbox-specific behaviors. Parameter *message* has the same meaning as with the `Message` constructor.

Messages in an mbox mailbox are stored together in a single file. The sender’s envelope address and the time of delivery are typically stored in a line beginning with “From ” that is used to indicate the start of a message, though there is considerable variation in the exact format of this data among mbox implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in *Status* and *X-Status* headers.

Conventional flags for mbox messages are as follows:

Flag	Meaning
R	Read
O	Previously detected by MUA
D	Marked for subsequent deletion
F	Marked as important
A	Replied to

The “R” and “O” flags are stored in the *Status* header, and the “D”, “F”, and “A” flags are stored in the *X-Status* header. The flags and headers typically appear in the order mentioned.

`mboxMessage` instances offer the following methods:

get_from()

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

set_from(*from_*, *time_* = *None*)

Set the “From ” line to *from_*, which should be specified without a leading “From ” or trailing newline. For convenience, *time_* may be specified and will be formatted appropriately and appended to *from_*. If *time_* is specified, it should be a **`time.struct_time`** instance, a tuple suitable for passing to **`time.strftime()`**, or `True` (to use **`time.gmtime()`**).

get_flags()

Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

set_flags(*flags*)

Set the flags specified by *flags* and unset all others. Parameter *flags* should be the concatenation in any order of zero or more occurrences of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

add_flag(*flag*)

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

remove_flag(*flag*)

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character.

When an `mboxMessage` instance is created based upon a `MaildirMessage` instance, a “From ” line is generated based upon the `MaildirMessage` instance’s delivery date, and the following conversions take place:

`MaildirMessage` state	Resulting state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

When an `mboxMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

`MHMessage` state	Resulting state
“unseen” sequence	O flag
“flagged” sequence	F flag
“replied” sequence	A flag

When an `mboxMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

`BabylMessage` state	Resulting state
“unseen” label	O flag
“deleted” label	D flag
“answered” label	A flag

When a `Message` instance is created based upon an `MMDFMessage` instance, the “From ” line is copied and all flags directly correspond:

`MMDFMessage` state	Resulting state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

MHMessage

class mailbox.MHMessage(*message*=*None*)

A message with MH-specific behaviors. Parameter *message* has the same meaning as with the `Message` constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard **mh** and **nmh**) use sequences in much the same way flags are used with other formats, as follows:

Sequence	Explanation
unseen	Not read, but previously detected by MUA
replied	Replied to
flagged	Marked as important

`MHMessage` instances offer the following methods:

get_sequences()

Return a list of the names of sequences that include this message.

set_sequences(*sequences*)

Set the list of sequences that include this message.

add_sequence(*sequence*)

Add *sequence* to the list of sequences that include this message.

remove_sequence(*sequence*)

Remove *sequence* from the list of sequences that include this message.

When an `MHMessage` instance is created based upon a `MaildirMessage` instance, the following conversions take place:

MaildirMessage state	Resulting state
“unseen” sequence	no S flag
“replied” sequence	R flag
“flagged” sequence	F flag

When an `MHMessage` instance is created based upon an `mboxMessage` or `MMDFMessage` instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

mboxMessage or MMDFMessage state	Resulting state
“unseen” sequence	no S flag
“replied” sequence	A flag
“flagged” sequence	F flag

When an `MHMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

BabylMessage state	Resulting state
“unseen” label	no S flag
“replied” label	A flag

BabylMessage

class mailbox.BabylMessage(*message*=*None*)

A message with Babyl-specific behaviors. Parameter *message* has the same meaning as with the `Message` constructor.

Certain message labels, called *attributes*, are defined by convention to have special meanings. The attributes are as follows:

Label	Explanation
unseen	Not read, but previously detected by MUA
deleted	Marked for subsequent deletion
filed	Copied to another file or mailbox
answered	Replied to
forwarded	Forwarded
edited	Modified by the user
resent	Resent

By default, Rmail displays only visible headers. The

BabylMessage class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

BabylMessage instances offer the following methods:

get_labels()

Return a list of labels on the message.

set_labels(*labels*)

Set the list of labels on the message to *labels*.

add_label(*label*)

Add *label* to the list of labels on the message.

remove_label(*label*)

Remove *label* from the list of labels on the message.

get_visible()

Return an **Message** instance whose headers are the message's visible headers and whose body is empty.

set_visible(*visible*)

Set the message's visible headers to be the same as the headers in *message*. Parameter *visible* should be a **Message** instance, an **email.message.Message** instance, a string, or a file-like object (which should be open in text mode).

update_visible()

When a **BabylMessage** instance's original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows: each visible header with a corresponding original header is set to the value of the original header, each visible header without a

corresponding original header is removed, and any of *Date*, *From*, *Reply-To*, *To*, *CC*, and *Subject* that are present in the original headers but not the visible headers are added to the visible headers.

When a `BabylMessage` instance is created based upon a `MaildirMessage` instance, the following conversions take place:

`MaildirMessage` state	resulting state
"S" flag	"seen" label
"T" flag	"deleted" label
"R" flag	"answered" label
"F" flag	"forwarded" label

When a `BabylMessage` instance is created based upon an `mboxMessage` or `MMDFMessage` instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

`mboxMessage` or `MMDFMessage` state	resulting state
"S" flag	"seen" label
"T" flag	"deleted" label
"A" flag	"answered" label

When a `BabylMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

`MHMessage` state	resulting state
"unseen" sequence	"unseen" label
"replied" sequence	"answered" label

`MMDFMessage`

class mailbox.MMDFMessage(*message*=*None*)

A message with MMDF-specific behaviors. Parameter *message* has the same meaning as with the `Message` constructor.

As with message in an mbox mailbox, MMDF messages are stored with the sender's address and the delivery date in an initial line beginning with "From ". Likewise, flags that indicate the state of the message are typically stored in *Status*

and *X-Status* headers.

Conventional flags for MMDF messages are identical to those of mbox message and are as follows:

Flag	Meaning
R	Read
O	Previously detected by MUA
D	Marked for subsequent deletion
F	Flagged as important
A	Replied to

The “R” and “O” flags are stored in the *Status* header, and the “D”, “F”, and “A” flags are stored in the *X-Status* header. The flags and headers typically appear in the order mentioned.

MMDFMessage instances offer the following methods, which are identical to those offered by **mboxMessage**:

get_from()

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

set_from(*from_*, *time_* = *None*)

Set the “From ” line to *from_*, which should be specified without a leading “From ” or trailing newline. For convenience, *time_* may be specified and will be formatted appropriately and appended to *from_*. If *time_* is specified, it should be a **time.struct_time** instance, a tuple suitable for passing to **time.strftime()**, or `True` (to use **time.gmtime()**).

get_flags()

Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of `'R'`, `'O'`,

`'D'`, `'F'`, and `'A'`.

set_flags(*flags*)

Set the flags specified by *flags* and unset all others. Parameter *flags* should be the concatenation in any order of zero or more occurrences of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

add_flag(*flag*)

Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

remove_flag(*flag*)

Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character.

When an **MMDFMessage** instance is created based upon a **MaildirMessage** instance, a “From ” line is generated based upon the **MaildirMessage** instance’s delivery date, and the following conversions take place:

MaildirMessage state	**MMDFMessage** state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

When an **MMDFMessage** instance is created based upon an **MHMessage** instance, the following conversions take place:

MHMessage state	**MMDFMessage** state
“replied” sequence	R flag
“flagged” sequence	F flag

When an **MMDFMessage** instance is created based upon a **BabylMessage** instance, the following conversions take place:

BabylMessage state	**MMDFMessage** state
“answered” flag	R flag
“forwarded” flag	O flag
“edited” flag	D flag
“resent” flag	D flag

When an **MMDFMessage** instance is created based upon a **BabylMessage** instance, the following conversions take place:

BabylMessage state	**Resulting state**
No flags or “unseen” label	R flag and O flag
“Unseen” label	No flags
“Deleted” label	D flag
“Answered” label	A flag

When an **MMDFMessage** instance is created based upon an **mboxMessage** instance, the “From ” line is copied and all flags directly correspond:

mboxMessage state	**Resulting state**
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

Exceptions

The following exception classes are defined in the **mailbox** module:

exception mailbox.Error

The based class for all other module-specific exceptions.

exception mailbox.NoSuchMailboxError

Raised when a mailbox is expected but is not found, such as when instantiating a **Mailbox** subclass with a path that does not exist (and with the *create* parameter set to `False`), or when opening a folder that does not exist.

exception mailbox.NotEmptyError

Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

exception mailbox.ExternalClashError

Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely generated file name already exists.

exception mailbox.FormatError

Raised when the data in a file cannot be parsed, such as when an **MH** instance attempts to read a corrupted `.mh_sequences` file.

Examples

A simple example of printing the subjects of all messages in a mailbox that seem interesting:

```
import mailbox
for message in mailbox.mbox('~/mbox'):
    subject = message['subject']       # Could possibly
    if subject and 'python' in subject.lower():
        print(subject)
```

To copy all mail from a Babyl mailbox to an MH mailbox, converting all of the format-specific information that can be converted:

```
import mailbox
destination = mailbox.MH('~/Mail')
destination.lock()
for message in mailbox.Babyl('~/RMAIL'):
    destination.add(mailbox.MHMessage(message))
destination.flush()
destination.unlock()
```

This example sorts mail from several mailing lists into different mailboxes, being careful to avoid mail corruption due to concurrent modification by other programs, mail loss due to interruption of the program, or premature termination due to malformed messages in the mailbox:

```
import mailbox
import email.errors

list_names = ('python-list', 'python-dev', 'python-bugs'

boxes = {name: mailbox.mbox('~/email/%s' % name) for nam
inbox = mailbox.Maildir('~/Maildir', factory=None)

for key in inbox.iterkeys():
    try:
        message = inbox[key]
    except email.errors.MessageParseError:
        continue                # The message is malform

    for name in list_names:
        list_id = message['list-id']
        if list_id and name in list_id:
            # Get mailbox to use
            box = boxes[name]

            # Write copy to disk before removing origina
            # If there's a crash, you might duplicate a
            # that's better than losing a message comple
            box.lock()
            box.add(message)
            box.flush()
            box.unlock()

            # Remove original message
            inbox.lock()
            inbox.discard(key)
            inbox.flush()
            inbox.unlock()
            break               # Found destination, so

for box in boxes.itervalues():
    box.close()
```

`mimetypes` — Map filenames to MIME types

Source code: Lib/mimetypes.py [https://github.com/python/cpython/tree/3.11/Lib/mimetypes.py]

The `mimetypes` module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call `init()` if they rely on the information `init()` sets up.

mimetypes.guess_type(*url*, *strict*=*True*)

Guess the type of a file based on its filename, path or URL, given by *url*. URL can be a string or a path-like object.

The return value is a tuple `(type, encoding)` where *type* is `None` if the type can't be guessed (missing or unknown suffix) or a string of the form `'type/subtype'`, usable for a MIME *content-type* header.

encoding is `None` for no encoding or the name of the program used to encode (e.g. **compress** or **gzip**). The encoding is suitable for use as a *Content-Encoding* header, **not** as a *Content-Transfer-Encoding* header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case sensitively, then case insensitively.

The optional *strict* argument is a flag specifying whether the list of known MIME types is limited to only the official types registered with IANA [https://www.iana.org/assignments/media-types/media-types.xhtml]. When *strict* is `True` (the default), only the IANA types are supported; when *strict* is `False`, some additional non-standard but commonly used MIME types are also recognized.

Changed in version 3.8: Added support for url being a path-like object.

mimetypes.guess_all_extensions(*type*, *strict*=*True*)

Guess the extensions for a file based on its MIME type, given by *type*. The return value is a list of strings giving all possible filename extensions, including the leading dot (`'.'`). The extensions are not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by **`guess_type()`**.

The optional *strict* argument has the same meaning as with the **`guess_type()`** function.

mimetypes.guess_extension(*type*, *strict*=*True*)

Guess the extension for a file based on its MIME type, given by *type*. The return value is a string giving a filename extension, including the leading dot (`'.'`). The extension is not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by **`guess_type()`**. If no extension can be guessed for *type*, `None` is returned.

The optional *strict* argument has the same meaning as with the **`guess_type()`** function.

Some additional functions and data items are available for controlling the behavior of the module.

mimetypes.init(*files*=*None*)

Initialize the internal data structures. If given, *files* must be a

sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from **knownfiles**; on Windows, the current registry settings are loaded. Each file named in *files* or **knownfiles** takes precedence over those named before it. Calling **init()** repeatedly is allowed.

Specifying an empty list for *files* will prevent the system defaults from being applied: only the well-known values will be present from a built-in list.

If *files* is `None` the internal data structure is completely rebuilt to its initial default value. This is a stable operation and will produce the same results when called multiple times.

Changed in version 3.2: Previously, Windows registry settings were ignored.

mimetypes.read_mime_types(*filename*)

Load the type map given in the file *filename*, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot (`'.'`), to strings of the form `'type/subtype'`. If the file *filename* does not exist or cannot be read, `None` is returned.

mimetypes.add_type(*type*, *ext*, *strict*=*True*)

Add a mapping from the MIME type *type* to the extension *ext*. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When *strict* is `True` (the default), the mapping will be added to the official MIME types, otherwise to the non-standard ones.

mimetypes.inited

Flag indicating whether or not the global data structures have been initialized. This is set to `True` by **init()**.

mimetypes.knownfiles

List of type map file names commonly installed. These files are typically named `mime.types` and are installed in different locations by different packages.

mimetypes.suffix_map

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately.

mimetypes.encodings_map

Dictionary mapping filename extensions to encoding types.

mimetypes.types_map

Dictionary mapping filename extensions to MIME types.

mimetypes.common_types

Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

An example usage of the module:

```
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
['/etc/mime.types', '/etc/httpd/mime.types', ... ]
>>> mimetypes.suffix_map['.tgz']
'.tar.gz'
>>> mimetypes.encodings_map['.gz']
'gzip'
>>> mimetypes.types_map['.tgz']
'application/x-tar-gz'
```

MimeTypes Objects

The **MimeTypes** class may be useful for applications which may want more than one MIME-type database; it provides an interface similar to the one of the **mimetypes** module.

class mimetypes.MimeTypes(*filenames* = *()*, *strict* = *True*)

This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional `mime.types`-style files into the database using the **read()** or **readfp()** methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional *filenames* parameter can be used to cause additional files to be loaded “on top” of the default database.

suffix_map

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately. This is initially a copy of the global **suffix_map** defined in the module.

encodings_map

Dictionary mapping filename extensions to encoding types. This is initially a copy of the global **encodings_map** defined in the module.

types_map

Tuple containing two dictionaries, mapping filename extensions to MIME types: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by **common_types** and **types_map**.

types_map_inv

Tuple containing two dictionaries, mapping MIME types to a list of filename extensions: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by **common_types** and **types_map**.

guess_extension(*type*, *strict*=*True*)

Similar to the **guess_extension()** function, using the tables stored as part of the object.

guess_type(*url*, *strict*=*True*)

Similar to the **guess_type()** function, using the tables stored as part of the object.

guess_all_extensions(*type*, *strict*=*True*)

Similar to the **guess_all_extensions()** function, using the tables stored as part of the object.

read(*filename*, *strict*=*True*)

Load MIME information from a file named *filename*. This uses **readfp()** to parse the file.

If *strict* is `True`, information will be added to list of standard types, else to the list of non-standard types.

readfp(*fp*, *strict*=*True*)

Load MIME type information from an open file *fp*. The file must have the format of the standard `mime.types` files.

If *strict* is `True`, information will be added to the list of standard types, else to the list of non-standard types.

read_windows_registry(*strict*=*True*)

Load MIME type information from the Windows registry.

Availability: Windows.

If *strict* is `True`, information will be added to the list of standard types, else to the list of non-standard types.

New in version 3.2.

`base64` — Base16, Base32, Base64, Base85 Data Encodings

Source code: Lib/base64.py [https://github.com/python/cpython/tree/3.11/Lib/base64.py]

This module provides functions for encoding binary data to printable ASCII characters and decoding such encodings back to binary data. It provides encoding and decoding functions for the encodings specified in **RFC 4648** [https://datatracker.ietf.org/doc/html/rfc4648.html], which defines the Base16, Base32, and Base64 algorithms, and for the de-facto standard Ascii85 and Base85 encodings.

The **RFC 4648** [https://datatracker.ietf.org/doc/html/rfc4648.html] encodings are suitable for encoding binary data so that it can be safely sent by email, used as parts of URLs, or included as part of an HTTP POST request. The encoding algorithm is not the same as the **uuencode** program.

There are two interfaces provided by this module. The modern interface supports encoding bytes-like objects to ASCII `bytes`, and decoding bytes-like objects or strings containing ASCII to `bytes`. Both base-64 alphabets defined in **RFC 4648** [https://datatracker.ietf.org/doc/html/rfc4648.html] (normal, and URL- and filesystem-safe) are supported.

The legacy interface does not support decoding from strings, but it does provide functions for encoding and decoding to and from file objects. It only supports the Base64 standard alphabet, and it adds newlines every 76 characters as per **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html]. Note that if you are looking for **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html] support you probably want to be looking at the `email` package instead.

Changed in version 3.3: ASCII-only Unicode strings are now accepted by the decoding functions of the modern interface.

Changed in version 3.4: Any bytes-like objects are now accepted by all encoding and decoding functions in this module. Ascii85/Base85 support added.

The modern interface provides:

base64.b64encode(*s*, *altchars*=*None*)

Encode the bytes-like object *s* using Base64 and return the encoded **bytes**.

Optional *altchars* must be a bytes-like object of length 2 which specifies an alternative alphabet for the `+` and `/` characters. This allows an application to e.g. generate URL or filesystem safe Base64 strings. The default is `None`, for which the standard Base64 alphabet is used.

May assert or raise a a **ValueError** if the length of *altchars* is not 2. Raises a **TypeError** if *altchars* is not a bytes-like object.

base64.b64decode(*s*, *altchars*=*None*, *validate*=*False*)

Decode the Base64 encoded bytes-like object or ASCII string *s* and return the decoded **bytes**.

Optional *altchars* must be a bytes-like object or ASCII string of length 2 which specifies the alternative alphabet used instead of the `+` and `/` characters.

A **binascii.Error** exception is raised if *s* is incorrectly padded.

If *validate* is `False` (the default), characters that are neither in the normal base-64 alphabet nor the alternative alphabet are discarded prior to the padding check. If *validate* is `True`, these non-alphabet characters in the input result in a **binascii.Error**.

For more information about the strict base64 check, see **binascii.a2b_base64()**

May assert or raise a **ValueError** if the length of *altchars* is not 2.

base64.standard_b64encode(*s*)

Encode bytes-like object *s* using the standard Base64 alphabet and return the encoded **bytes**.

base64.standard_b64decode(*s*)

Decode bytes-like object or ASCII string *s* using the standard Base64 alphabet and return the decoded **bytes**.

base64.urlsafe_b64encode(*s*)

Encode bytes-like object *s* using the URL- and filesystem-safe alphabet, which substitutes `-` instead of `+` and `_` instead of `/` in the standard Base64 alphabet, and return the encoded **bytes**. The result can still contain `=`.

base64.urlsafe_b64decode(*s*)

Decode bytes-like object or ASCII string *s* using the URL- and filesystem-safe alphabet, which substitutes `-` instead of `+` and `_` instead of `/` in the standard Base64 alphabet, and return the decoded **bytes**.

base64.b32encode(*s*)

Encode the bytes-like object *s* using Base32 and return the encoded **bytes**.

base64.b32decode(*s*, *casefold*=*False*, *map01*=*None*)

Decode the Base32 encoded bytes-like object or ASCII string *s* and return the decoded **bytes**.

Optional *casefold* is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is `False`.

RFC 4648 [https://datatracker.ietf.org/doc/html/rfc4648.html] allows for optional mapping of the digit 0 (zero) to the letter O (oh), and for optional mapping of the digit 1 (one) to either the letter I (eye) or letter L (el). The optional argument *map01* when not `None`, specifies which letter the digit 1 should be mapped to (when *map01* is not `None`, the digit 0 is always mapped to the letter O). For security purposes the default is `None`, so that 0 and 1 are not allowed in the input.

A **`binascii.Error`** is raised if *s* is incorrectly padded or if there are non-alphabet characters present in the input.

base64.b32hexencode(*s*)

Similar to **`b32encode()`** but uses the Extended Hex Alphabet, as defined in **RFC 4648** [https://datatracker.ietf.org/doc/html/rfc4648.html].

New in version 3.10.

base64.b32hexdecode(*s*, *casefold*=*False*)

Similar to **`b32decode()`** but uses the Extended Hex Alphabet, as defined in **RFC 4648** [https://datatracker.ietf.org/doc/html/rfc4648.html].

This version does not allow the digit 0 (zero) to the letter O (oh) and digit 1 (one) to either the letter I (eye) or letter L (el) mappings, all these characters are included in the Extended Hex Alphabet and are not interchangeable.

New in version 3.10.

base64.b16encode(*s*)

Encode the bytes-like object *s* using Base16 and return the encoded **`bytes`**.

base64.b16decode(*s*, *casefold*=*False*)

Decode the Base16 encoded bytes-like object or ASCII string *s* and return the decoded **`bytes`**.

Optional *casefold* is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is `False`.

A **`binascii.Error`** is raised if *s* is incorrectly padded or if there are non-alphabet characters present in the input.

base64.a85encode(*b*, *, *foldspaces=False*, *wrapcol=0*, *pad=False*, *adobe=False*)

Encode the bytes-like object *b* using Ascii85 and return the encoded **`bytes`**.

foldspaces is an optional flag that uses the special short sequence 'y' instead of 4 consecutive spaces (ASCII 0x20) as supported by 'btoa'. This feature is not supported by the "standard" Ascii85 encoding.

wrapcol controls whether the output should have newline (`b'\n'`) characters added to it. If this is non-zero, each output line will be at most this many characters long.

pad controls whether the input is padded to a multiple of 4 before encoding. Note that the `btoa` implementation always pads.

adobe controls whether the encoded byte sequence is framed with `<~` and `~>`, which is used by the Adobe implementation.

New in version 3.4.

base64.a85decode(*b*, *, *foldspaces=False*, *adobe=False*, *ignorechars=b' \t\n\r\x0b'*)

Decode the Ascii85 encoded bytes-like object or ASCII string *b* and return the decoded **`bytes`**.

foldspaces is a flag that specifies whether the 'y' short sequence should be accepted as shorthand for 4 consecutive spaces (ASCII 0x20). This feature is not supported by the "standard" Ascii85 encoding.

adobe controls whether the input sequence is in Adobe Ascii85 format (i.e. is framed with <~ and ~>).

ignorechars should be a bytes-like object or ASCII string containing characters to ignore from the input. This should only contain whitespace characters, and by default contains all whitespace characters in ASCII.

New in version 3.4.

base64.b85encode(*b*, *pad*=*False*)

Encode the bytes-like object *b* using base85 (as used in e.g. git-style binary diffs) and return the encoded **bytes**.

If *pad* is true, the input is padded with `b'\0'` so its length is a multiple of 4 bytes before encoding.

New in version 3.4.

base64.b85decode(*b*)

Decode the base85-encoded bytes-like object or ASCII string *b* and return the decoded **bytes**. Padding is implicitly removed, if necessary.

New in version 3.4.

The legacy interface:

base64.decode(*input*, *output*)

Decode the contents of the binary *input* file and write the resulting binary data to the *output* file. *input* and *output* must be file objects. *input* will be read until `input.readline()` returns an empty bytes object.

base64.decodebytes(*s*)

Decode the bytes-like object *s*, which must contain one or more lines of base64 encoded data, and return the decoded **bytes**.

New in version 3.1.

base64.encode(*input*, *output*)

Encode the contents of the binary *input* file and write the resulting base64 encoded data to the *output* file. *input* and *output* must be file objects. *input* will be read until `input.read()` returns an empty bytes object. **`encode()`** inserts a newline character (`b'\n'`) after every 76 bytes of the output, as well as ensuring that the output always ends with a newline, as per **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html] (MIME).

base64.encodebytes(*s*)

Encode the bytes-like object *s*, which can contain arbitrary binary data, and return **`bytes`** containing the base64-encoded data, with newlines (`b'\n'`) inserted after every 76 bytes of output, and ensuring that there is a trailing newline, as per **RFC 2045** [https://datatracker.ietf.org/doc/html/rfc2045.html] (MIME).

New in version 3.1.

An example usage of the module:

```
>>> import base64
>>> encoded = base64.b64encode(b'data to be encoded')
>>> encoded
b'ZGF0YSB0byBiZSBlbmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
b'data to be encoded'
```

Security Considerations

A new security considerations section was added to **RFC 4648** [https://datatracker.ietf.org/doc/html/rfc4648.html] (section 12); it's recommended to review the security section for any code deployed to production.

Module `binascii`
: Support module containing ASCII-to-binary and binary-to-ASCII conversions.

RFC 1521 [https://datatracker.ietf.org/doc/html/rfc1521.html] - MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies
: Section 5.2, “Base64 Content-Transfer-Encoding,” provides the definition of the base64 encoding.

`binascii` — Convert between binary and ASCII

The `binascii` module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like `uu` or `base64` instead. The `binascii` module contains low-level functions written in C for greater speed that are used by the higher-level modules.

Note

`a2b_*` functions accept Unicode strings containing only ASCII characters. Other functions only accept bytes-like objects (such as `bytes`, `bytearray` and other objects that support the buffer protocol).

Changed in version 3.3: ASCII-only unicode strings are now accepted by the `a2b_*` functions.

The `binascii` module defines the following functions:

binascii.a2b_uu(*string*)

Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

binascii.b2a_uu(*data*, *, *backtick*=*False*)

Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of *data* should be at most 45. If *backtick* is true, zeros are represented by `'`'` instead of spaces.

Changed in version 3.7: Added the *backtick* parameter.

binascii.a2b_base64(*string*, /, *, *strict_mode*=*False*)

Convert a block of base64 data back to binary and return the binary data. More than one line may be passed at a time.

If *strict_mode* is true, only valid base64 data will be converted. Invalid base64 data will raise **binascii.Error**.

Valid base64:

- Conforms to **RFC 3548** [https://datatracker.ietf.org/doc/html/rfc3548.html].
- Contains only characters from the base64 alphabet.
- Contains no excess data after padding (including excess padding, newlines, etc.).
- Does not start with a padding.

Changed in version 3.11: Added the *strict_mode* parameter.

binascii.b2a_base64(*data*, *, *newline*=*True*)

Convert binary data to a line of ASCII characters in base64 coding. The return value is the converted line, including a newline char if *newline* is true. The output of this function conforms to **RFC 3548** [https://datatracker.ietf.org/doc/html/rfc3548.html].

Changed in version 3.6: Added the *newline* parameter.

binascii.a2b_qp(*data*, *header*=*False*)

Convert a block of quoted-printable data back to binary and return the binary data. More than one line may be passed at a time. If the optional argument *header* is present and true, underscores will be decoded as spaces.

binascii.b2a_qp(*data*, *quotetabs*=*False*, *istext*=*True*, *header*=*False*)

Convert binary data to a line(s) of ASCII characters in quoted-printable encoding. The return value is the converted line(s).

If the optional argument *quotetabs* is present and true, all tabs and spaces will be encoded. If the optional argument *istext* is present and true, newlines are not encoded but trailing whitespace will be encoded. If the optional argument *header* is present and true, spaces will be encoded as underscores per **RFC 1522** [https://datatracker.ietf.org/doc/html/rfc1522.html]. If the optional argument *header* is present and false, newline characters will be encoded as well; otherwise linefeed conversion might corrupt the binary data stream.

binascii.crc_hqx(*data*, *value*)

Compute a 16-bit CRC value of *data*, starting with *value* as the initial CRC, and return the result. This uses the CRC-CCITT polynomial $x^{16} + x^{12} + x^5 + 1$, often represented as 0x1021. This CRC is used in the binhex4 format.

binascii.crc32(*data*[, *value*])

Compute CRC-32, the unsigned 32-bit checksum of *data*, starting with an initial CRC of *value*. The default initial CRC is zero. The algorithm is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows:

```
print(binascii.crc32(b"hello world"))
# Or, in two pieces:
crc = binascii.crc32(b"hello")
crc = binascii.crc32(b" world", crc)
print('crc32 = {:#010x}'.format(crc))
```

Changed in version 3.0: The result is always unsigned.

binascii.b2a_hex(*data*[, *sep*[, *bytes_per_sep*=*1*]])
binascii.hexlify(*data*[, *sep*[, *bytes_per_sep*=*1*]])

Return the hexadecimal representation of the binary *data*. Every byte of *data* is converted into the corresponding 2-digit hex representation. The returned bytes object is therefore twice as long as the length of *data*.

Similar functionality (but returning a text string) is also conveniently accessible using the **bytes.hex()** method.

If *sep* is specified, it must be a single character str or bytes object. It will be inserted in the output after every *bytes_per_sep* input bytes. Separator placement is counted from the right end of the output by default, if you wish to count from the left, supply a negative *bytes_per_sep* value.

```
>>> import binascii
>>> binascii.b2a_hex(b'\xb9\x01\xef')
b'b901ef'
>>> binascii.hexlify(b'\xb9\x01\xef', '-')
b'b9-01-ef'
>>> binascii.b2a_hex(b'\xb9\x01\xef', b'_', 2)
b'b9_01ef'
>>> binascii.b2a_hex(b'\xb9\x01\xef', b' ', -2)
b'b901 ef'
```

Changed in version 3.8: The *sep* and *bytes_per_sep* parameters were added.

binascii.a2b_hex(*hexstr*)

binascii.unhexlify(*hexstr*)

Return the binary data represented by the hexadecimal string *hexstr*. This function is the inverse of **b2a_hex()**. *hexstr* must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise an **Error** exception is raised.

Similar functionality (accepting only text string arguments, but more liberal towards whitespace) is also accessible using the **bytes.fromhex()** class method.

exception binascii.Error

Exception raised on errors. These are usually programming errors.

exception binascii.Incomplete

Exception raised on incomplete data. These are usually not programming errors, but may be handled by reading a little more data and trying again.

See also

Module `base64`
Support for RFC compliant base64-style encoding in base 16, 32, 64, and 85.

Module `uu`
Support for UU encoding used on Unix.

Module `quopri`
Support for quoted-printable encoding used in MIME email messages.

`quopri` — Encode and decode MIME quoted-printable data

Source code: Lib/quopri.py [https://github.com/python/cpython/tree/3.11/Lib/quopri.py]

This module performs quoted-printable transport encoding and decoding, as defined in **RFC 1521** [https://datatracker.ietf.org/doc/html/rfc1521.html]: "MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies". The quoted-printable encoding is designed for data where there are relatively few nonprintable characters; the base64 encoding scheme available via the `base64` module is more compact if there are many such characters, as when sending a graphics file.

quopri.decode(*input*, *output*, *header*=*False*)

Decode the contents of the *input* file and write the resulting decoded binary data to the *output* file. *input* and *output* must be binary file objects. If the optional argument *header* is present and true, underscore will be decoded as space. This is used to decode "Q"-encoded headers as described in **RFC 1522** [https://datatracker.ietf.org/doc/html/rfc1522.html]: "MIME (Multipurpose Internet Mail Extensions) Part Two: Message Header Extensions for Non-ASCII Text".

quopri.encode(*input*, *output*, *quotetabs*, *header*=*False*)

Encode the contents of the *input* file and write the resulting quoted-printable data to the *output* file. *input* and *output* must be binary file objects. *quotetabs*, a non-optional flag which controls whether to encode embedded spaces and tabs; when true it encodes such embedded whitespace, and when false it leaves them unencoded. Note that spaces and tabs appearing

at the end of lines are always encoded, as per **RFC 1521** [https://datatracker.ietf.org/doc/html/rfc1521.html]. *header* is a flag which controls if spaces are encoded as underscores as per **RFC 1522** [https://datatracker.ietf.org/doc/html/rfc1522.html].

quopri.decodestring(*s*, *header*=*False*)

Like **`decode()`**, except that it accepts a source **`bytes`** and returns the corresponding decoded **`bytes`**.

quopri.encodestring(*s*, *quotetabs*=*False*, *header*=*False*)

Like **`encode()`**, except that it accepts a source **`bytes`** and returns the corresponding encoded **`bytes`**. By default, it sends a `False` value to *quotetabs* parameter of the **`encode()`** function.

`html` — HyperText Markup Language support

Source code: Lib/html/__init__.py [https://github.com/python/cpython/tree/3.11/Lib/html/__init__.py]

This module defines utilities to manipulate HTML.

html.escape(*s*, *quote=True*)

Convert the characters `&`, `<` and `>` in string *s* to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag *quote* is true, the characters (`"`) and (`'`) are also translated; this helps for inclusion in an HTML attribute value delimited by quotes, as in `<a href="...">`.

New in version 3.2.

html.unescape(*s*)

Convert all named and numeric character references (e.g. `>`, `>`, `>`) in the string *s* to the corresponding Unicode characters. This function uses the rules defined by the HTML 5 standard for both valid and invalid character references, and the **list of HTML 5 named character references**.

New in version 3.4.

Submodules in the `html` package are:

- **`html.parser`** – HTML/XHTML parser with lenient parsing mode
- **`html.entities`** – HTML entity definitions

`html.parser` — Simple HTML and XHTML parser

Source code: Lib/html/parser.py [https://github.com/python/cpython/tree/3.11/Lib/html/parser.py]

This module defines a class `HTMLParser` which serves as the basis for parsing text files formatted in HTML (HyperText Mark-up Language) and XHTML.

class html.parser.HTMLParser(**, convert_charrefs=True*)

Create a parser instance able to parse invalid markup.

If *convert_charrefs* is `True` (the default), all character references (except the ones in `script/style` elements) are automatically converted to the corresponding Unicode characters.

An `HTMLParser` instance is fed HTML data and calls handler methods when start tags, end tags, text, comments, and other markup elements are encountered. The user should subclass `HTMLParser` and override its methods to implement the desired behavior.

This parser does not check that end tags match start tags or call the end-tag handler for elements which are closed implicitly by closing an outer element.

Changed in version 3.4: convert_charrefs keyword argument added.

Changed in version 3.5: The default value for argument *convert_charrefs* is now `True`.

Example HTML Parser Application

As a basic example, below is a simple HTML parser that uses the **`HTMLParser`** class to print out start tags, end tags, and data as they are encountered:

```
from html.parser import HTMLParser

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Encountered a start tag:", tag)

    def handle_endtag(self, tag):
        print("Encountered an end tag :", tag)

    def handle_data(self, data):
        print("Encountered some data  :", data)

parser = MyHTMLParser()
parser.feed('<html><head><title>Test</title></head>'
            '<body><h1>Parse me!</h1></body></html>')
```

The output will then be:

```
Encountered a start tag: html
Encountered a start tag: head
Encountered a start tag: title
Encountered some data  : Test
Encountered an end tag : title
Encountered an end tag : head
Encountered a start tag: body
Encountered a start tag: h1
Encountered some data  : Parse me!
Encountered an end tag : h1
Encountered an end tag : body
Encountered an end tag : html
```

`HTMLParser` Methods

HTMLParser instances have the following methods:

HTMLParser.feed(*data*)

Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or **close()** is called. *data* must be **str**.

HTMLParser.close()

Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call the **HTMLParser** base class method **close()**.

HTMLParser.reset()

Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

HTMLParser.getpos()

Return current line number and offset.

HTMLParser.get_starttag_text()

Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML “as deployed” or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

The following methods are called when data or markup elements are encountered and they are meant to be overridden in a subclass. The base class implementations do nothing (except for **handle_startendtag()**):

HTMLParser.handle_starttag(*tag*, *attrs*)

This method is called to handle the start tag of an element (e.g. `<div id="main">`).

The *tag* argument is the name of the tag converted to lower case. The *attrs* argument is a list of `(name, value)` pairs containing the attributes found inside the tag's `<>` brackets. The *name* will be translated to lower case, and quotes in the *value* have been removed, and character and entity references have been replaced.

For instance, for the tag `<A HREF="https://www.cwi.nl/">`, this method would be called as `handle_starttag('a', [('href', 'https://www.cwi.nl/')])`.

All entity references from **`html.entities`** are replaced in the attribute values.

HTMLParser.handle_endtag(*tag*)

This method is called to handle the end tag of an element (e.g. `</div>`).

The *tag* argument is the name of the tag converted to lower case.

HTMLParser.handle_startendtag(*tag*, *attrs*)

Similar to **`handle_starttag()`**, but called when the parser encounters an XHTML-style empty tag (`<img ... />`). This method may be overridden by subclasses which require this particular lexical information; the default implementation simply calls **`handle_starttag()`** and **`handle_endtag()`**.

HTMLParser.handle_data(*data*)

This method is called to process arbitrary data (e.g. text nodes and the content of `<script>...</script>` and `<style>...</style>`).

HTMLParser.handle_entityref(*name*)

This method is called to process a named character reference of the form `&name;` (e.g. `>`), where *name* is a general entity

reference (e.g. `'gt'`). This method is never called if *convert_charrefs* is `True`.

HTMLParser.handle_charref(*name*)

This method is called to process decimal and hexadecimal numeric character references of the form `&#NNN;` and `&#xNNN;`. For example, the decimal equivalent for `>` is `>`, whereas the hexadecimal is `>`; in this case the method will receive `'62'` or `'x3E'`. This method is never called if *convert_charrefs* is `True`.

HTMLParser.handle_comment(*data*)

This method is called when a comment is encountered (e.g. `<!--comment-->`).

For example, the comment `<!-- comment -->` will cause this method to be called with the argument `' comment '`.

The content of Internet Explorer conditional comments (condcoms) will also be sent to this method, so, for `<!--[if IE 9]>IE9-specific content<![endif]-->`, this method will receive `'[if IE 9]>IE9-specific content<![endif]'`.

HTMLParser.handle_decl(*decl*)

This method is called to handle an HTML doctype declaration (e.g. `<!DOCTYPE html>`).

The *decl* parameter will be the entire contents of the declaration inside the `<!...>` markup (e.g. `'DOCTYPE html'`).

HTMLParser.handle_pi(*data*)

Method called when a processing instruction is encountered. The *data* parameter will contain the entire processing instruction. For example, for the processing instruction `<?proc color='red'>`, this method would be called as `handle_pi("proc color='red'")`. It is intended to be

overridden by a derived class; the base class implementation does nothing.

Note

The **`HTMLParser`** class uses the SGML syntactic rules for processing instructions. An XHTML processing instruction using the trailing `'?'` will cause the `'?'` to be included in *data*.

HTMLParser.unknown_decl(*data*)

This method is called when an unrecognized declaration is read by the parser.

The *data* parameter will be the entire contents of the declaration inside the `<![...]>` markup. It is sometimes useful to be overridden by a derived class. The base class implementation does nothing.

Examples

The following class implements a parser that will be used to illustrate more examples:

```
from html.parser import HTMLParser
from html.entities import name2codepoint

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Start tag:", tag)
        for attr in attrs:
            print("     attr:", attr)

    def handle_endtag(self, tag):
        print("End tag  :", tag)

    def handle_data(self, data):
```

```
        print("Data     :", data)

    def handle_comment(self, data):
        print("Comment  :", data)

    def handle_entityref(self, name):
        c = chr(name2codepoint[name])
        print("Named ent:", c)

    def handle_charref(self, name):
        if name.startswith('x'):
            c = chr(int(name[1:], 16))
        else:
            c = chr(int(name))
        print("Num ent  :", c)

    def handle_decl(self, data):
        print("Decl     :", data)

parser = MyHTMLParser()
```

Parsing a doctype:

```
>>> parser.feed('<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML
...             '"http://www.w3.org/TR/html4/strict.dtd"
Decl     : DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//E
```

Parsing an element with a few attributes and a title:

```
>>> parser.feed('<img src="python-logo.png" alt="The Pyt
Start tag: img
     attr: ('src', 'python-logo.png')
     attr: ('alt', 'The Python logo')
>>>
>>> parser.feed('<h1>Python</h1>')
Start tag: h1
Data     : Python
End tag  : h1
```

The content of `script` and `style` elements is returned as is, without further parsing:

```
>>> parser.feed('<style type="text/css">#python { color:
Start tag: style
     attr: ('type', 'text/css')
Data     : #python { color: green }
End tag  : style

>>> parser.feed('<script type="text/javascript">'
...              'alert("<strong>hello!</strong>");</scri
Start tag: script
     attr: ('type', 'text/javascript')
Data     : alert("<strong>hello!</strong>");
End tag  : script
```

Parsing comments:

```
>>> parser.feed('<!-- a comment -->'
...              '<!--[if IE 9]>IE-specific content<![enc
Comment  :  a comment
Comment  : [if IE 9]>IE-specific content<![endif]
```

Parsing named and numeric character references and converting them to the correct char (note: these 3 references are all equivalent to `'>'`):

```
>>> parser.feed('&gt;&#62;&#x3e;')
Named ent: >
Num ent  : >
Num ent  : >
```

Feeding incomplete chunks to **`feed()`** works, but **`handle_data()`** might be called more than once (unless *convert_charrefs* is set to `True`):

```
>>> for chunk in ['<sp', 'an>buff', 'ered ', 'text</s',
...     parser.feed(chunk)
...
Start tag: span
```

```
Data     : buff
Data     : ered
Data     : text
End tag  : span
```

Parsing invalid HTML (e.g. unquoted attributes) also works:

```
>>> parser.feed('<p><a class=link href=#main>tag soup</p
Start tag: p
Start tag: a
     attr: ('class', 'link')
     attr: ('href', '#main')
Data     : tag soup
End tag  : p
End tag  : a
```

`html.entities` — Definitions of HTML general entities

Source code: Lib/html/entities.py [https://github.com/python/cpython/tree/3.11/Lib/html/entities.py]

This module defines four dictionaries, `html5`, `name2codepoint`, `codepoint2name`, and `entitydefs`.

html.entities.html5

A dictionary that maps HTML5 named character references [1] to the equivalent Unicode character(s), e.g. `html5['gt;'] == '>'`. Note that the trailing semicolon is included in the name (e.g. `'gt;'`), however some of the names are accepted by the standard even without the semicolon: in this case the name is present with and without the `';'`. See also `html.unescape()`.

New in version 3.3.

html.entities.entitydefs

A dictionary mapping XHTML 1.0 entity definitions to their replacement text in ISO Latin-1.

html.entities.name2codepoint

A dictionary that maps HTML entity names to the Unicode code points.

html.entities.codepoint2name

A dictionary that maps Unicode code points to HTML entity names.

Footnotes

See https://html.spec.whatwg.org/multipage/named-characters.html#named-character-references

XML Processing Modules

Source code: Lib/xml/ [https://github.com/python/cpython/tree/3.11/Lib/xml/]

Python's interfaces for processing XML are grouped in the `xml` package.

Warning

The XML modules are not secure against erroneous or maliciously constructed data. If you need to parse untrusted or unauthenticated data see the XML vulnerabilities and The defusedxml Package sections.

It is important to note that modules in the **`xml`** package require that there be at least one SAX-compliant XML parser available. The Expat parser is included with Python, so the **`xml.parsers.expat`** module will always be available.

The documentation for the **`xml.dom`** and **`xml.sax`** packages are the definition of the Python bindings for the DOM and SAX interfaces.

The XML handling submodules are:

- **`xml.etree.ElementTree`**: the ElementTree API, a simple and lightweight XML processor

- **`xml.dom`**: the DOM API definition
- **`xml.dom.minidom`**: a minimal DOM implementation
- **`xml.dom.pulldom`**: support for building partial DOM trees

- **`xml.sax`**: SAX2 base classes and convenience functions
- **`xml.parsers.expat`**: the Expat parser binding

XML vulnerabilities

The XML processing modules are not secure against maliciously constructed data. An attacker can abuse XML features to carry out denial of service attacks, access local files, generate network connections to other machines, or circumvent firewalls.

The following table gives an overview of the known attacks and whether the various modules are vulnerable to them.

1. Expat 2.4.1 and newer is not vulnerable to the “billion laughs” and “quadratic blowup” vulnerabilities. Items still listed as vulnerable due to potential reliance on system-provided libraries. Check **`pyexpat.EXPAT_VERSION`**.
2. **`xml.etree.ElementTree`** doesn’t expand external entities and raises a **`ParserError`** when an entity occurs.
3. **`xml.dom.minidom`** doesn’t expand external entities and simply returns the unexpanded entity verbatim.
4. **`xmlrpclib`** doesn’t expand external entities and omits them.
5. Since Python 3.7.1, external general entities are no longer processed by default.

billion laughs / exponential entity expansion
: The Billion Laughs [https://en.wikipedia.org/wiki/Billion_laughs] attack – also known as exponential entity expansion – uses multiple levels of nested entities. Each entity refers to another entity several times, and the final entity definition contains a small string. The exponential expansion results in several gigabytes of text and consumes lots of memory and CPU time.

quadratic blowup entity expansion
: A quadratic blowup attack is similar to a Billion Laughs [https://en.wikipedia.org/wiki/Billion_laughs] attack; it abuses entity

expansion, too. Instead of nested entities it repeats one large entity with a couple of thousand chars over and over again. The attack isn't as efficient as the exponential case but it avoids triggering parser countermeasures that forbid deeply nested entities.

external entity expansion
: Entity declarations can contain more than just text for replacement. They can also point to external resources or local files. The XML parser accesses the resource and embeds the content into the XML document.

DTD [https://en.wikipedia.org/wiki/Document_type_definition] retrieval
: Some XML libraries like Python's `xml.dom.pulldom` retrieve document type definitions from remote or local locations. The feature has similar implications as the external entity expansion issue.

decompression bomb
: Decompression bombs (aka ZIP bomb [https://en.wikipedia.org/wiki/Zip_bomb]) apply to all XML libraries that can parse compressed XML streams such as gzipped HTTP streams or LZMA-compressed files. For an attacker it can reduce the amount of transmitted data by three magnitudes or more.

The documentation for defusedxml [https://pypi.org/project/defusedxml/] on PyPI has further information about all known attack vectors with examples and references.

The `defusedxml` Package

defusedxml [https://pypi.org/project/defusedxml/] is a pure Python package with modified subclasses of all stdlib XML parsers that prevent any potentially malicious operation. Use of this package is recommended for any server code that parses untrusted XML data. The package also ships with example exploits and extended documentation on more XML exploits such as XPath injection.

`xml.etree.ElementTree` — The ElementTree XML API

Source code: Lib/xml/etree/ElementTree.py [https://github.com/python/cpython/tree/3.11/Lib/xml/etree/ElementTree.py]

The `xml.etree.ElementTree` module implements a simple and efficient API for parsing and creating XML data.

Changed in version 3.3: This module will use a fast implementation whenever available.

Deprecated since version 3.3: The `xml.etree.cElementTree` module is deprecated.

Warning

The `xml.etree.ElementTree` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

Tutorial

This is a short tutorial for using `xml.etree.ElementTree` (`ET` in short). The goal is to demonstrate some of the building blocks and basic concepts of the module.

XML tree and elements

XML is an inherently hierarchical data format, and the most natural way to represent it is with a tree. `ET` has two classes for this purpose - `ElementTree` represents the whole XML document as a tree, and `Element` represents a single node in this tree.

Interactions with the whole document (reading and writing to/from files) are usually done on the **`ElementTree`** level. Interactions with a single XML element and its sub-elements are done on the **`Element`** level.

Parsing XML

We'll be using the following XML document as the sample data for this section:

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank>1</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank>4</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
    <country name="Panama">
        <rank>68</rank>
        <year>2011</year>
        <gdppc>13600</gdppc>
        <neighbor name="Costa Rica" direction="W"/>
        <neighbor name="Colombia" direction="E"/>
    </country>
</data>
```

We can import this data by reading from a file:

```
import xml.etree.ElementTree as ET
tree = ET.parse('country_data.xml')
root = tree.getroot()
```

Or directly from a string:

```
root = ET.fromstring(country_data_as_string)
```

`fromstring()` parses XML from a string directly into an **`Element`**, which is the root element of the parsed tree. Other parsing functions may create an **`ElementTree`**. Check the documentation to be sure.

As an **`Element`**, `root` has a tag and a dictionary of attributes:

```
>>> root.tag
'data'
>>> root.attrib
{}
```

It also has children nodes over which we can iterate:

```
>>> for child in root:
...     print(child.tag, child.attrib)
...
country {'name': 'Liechtenstein'}
country {'name': 'Singapore'}
country {'name': 'Panama'}
```

Children are nested, and we can access specific child nodes by index:

```
>>> root[0][1].text
'2008'
```

Note

Not all elements of the XML input will end up as elements of the parsed tree. Currently, this module skips over any XML comments, processing instructions, and document type declarations in the input. Nevertheless, trees built using this module's API rather than parsing from XML text can have comments and processing instructions in them; they will be included when generating XML output. A document type declaration may be accessed by passing a custom **`TreeBuilder`**

instance to the **`XMLParser`** constructor.

Pull API for non-blocking parsing

Most parsing functions provided by this module require the whole document to be read at once before returning any result. It is possible to use an **`XMLParser`** and feed data into it incrementally, but it is a push API that calls methods on a callback target, which is too low-level and inconvenient for most needs. Sometimes what the user really wants is to be able to parse XML incrementally, without blocking operations, while enjoying the convenience of fully constructed **`Element`** objects.

The most powerful tool for doing this is **`XMLPullParser`**. It does not require a blocking read to obtain the XML data, and is instead fed with data incrementally with **`XMLPullParser.feed()`** calls. To get the parsed XML elements, call **`XMLPullParser.read_events()`**. Here is an example:

```
>>> parser = ET.XMLPullParser(['start', 'end'])
>>> parser.feed('<mytag>sometext')
>>> list(parser.read_events())
[('start', <Element 'mytag' at 0x7fa66db2be58>)]
>>> parser.feed(' more text</mytag>')
>>> for event, elem in parser.read_events():
...     print(event)
...     print(elem.tag, 'text=', elem.text)
...
end
```

The obvious use case is applications that operate in a non-blocking fashion where the XML data is being received from a socket or read incrementally from some storage device. In such cases, blocking reads are unacceptable.

Because it's so flexible, **`XMLPullParser`** can be inconvenient to use for simpler use-cases. If you don't mind your application blocking on reading XML data but would still like to have incremental parsing capabilities, take a look at **`iterparse()`**. It can be useful when you're reading a large XML document and don't

want to hold it wholly in memory.

Finding interesting elements

`Element` has some useful methods that help iterate recursively over all the sub-tree below it (its children, their children, and so on). For example, `Element.iter()`:

```
>>> for neighbor in root.iter('neighbor'):
...     print(neighbor.attrib)
...
{'name': 'Austria', 'direction': 'E'}
{'name': 'Switzerland', 'direction': 'W'}
{'name': 'Malaysia', 'direction': 'N'}
{'name': 'Costa Rica', 'direction': 'W'}
{'name': 'Colombia', 'direction': 'E'}
```

`Element.findall()` finds only elements with a tag which are direct children of the current element. `Element.find()` finds the *first* child with a particular tag, and `Element.text` accesses the element's text content. `Element.get()` accesses the element's attributes:

```
>>> for country in root.findall('country'):
...     rank = country.find('rank').text
...     name = country.get('name')
...     print(name, rank)
...
Liechtenstein 1
Singapore 4
Panama 68
```

More sophisticated specification of which elements to look for is possible by using XPath.

Modifying an XML File

`ElementTree` provides a simple way to build XML documents and write them to files. The `ElementTree.write()` method serves this purpose.

Once created, an `Element` object may be manipulated by directly changing its fields (such as `Element.text`), adding and modifying attributes (`Element.set()` method), as well as adding new children (for example with `Element.append()`).

Let's say we want to add one to each country's rank, and add an `updated` attribute to the rank element:

```
>>> for rank in root.iter('rank'):
...     new_rank = int(rank.text) + 1
...     rank.text = str(new_rank)
...     rank.set('updated', 'yes')
...
>>> tree.write('output.xml')
```

Our XML now looks like this:

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
    <country name="Panama">
        <rank updated="yes">69</rank>
        <year>2011</year>
        <gdppc>13600</gdppc>
        <neighbor name="Costa Rica" direction="W"/>
        <neighbor name="Colombia" direction="E"/>
    </country>
```

```
</data>
```

We can remove elements using `Element.remove()`. Let's say we want to remove all countries with a rank higher than 50:

```
>>> for country in root.findall('country'):
...     # using root.findall() to avoid removal during t
...     rank = int(country.find('rank').text)
...     if rank > 50:
...         root.remove(country)
...
>>> tree.write('output.xml')
```

Note that concurrent modification while iterating can lead to problems, just like when iterating and modifying Python lists or dicts. Therefore, the example first collects all matching elements with `root.findall()`, and only then iterates over the list of matches.

Our XML now looks like this:

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
</data>
```

Building XML documents

The `SubElement()` function also provides a convenient way to create new sub-elements for a given element:

```
>>> a = ET.Element('a')
>>> b = ET.SubElement(a, 'b')
>>> c = ET.SubElement(a, 'c')
>>> d = ET.SubElement(c, 'd')
>>> ET.dump(a)
<a><b /><c><d /></c></a>
```

Parsing XML with Namespaces

If the XML input has namespaces [https://en.wikipedia.org/wiki/XML_namespace], tags and attributes with prefixes in the form `prefix:sometag` get expanded to `{uri}sometag` where the *prefix* is replaced by the full *URI*. Also, if there is a default namespace [https://www.w3.org/TR/xml-names/#defaulting], that full URI gets prepended to all of the non-prefixed tags.

Here is an XML example that incorporates two namespaces, one with the prefix "fictional" and the other serving as the default namespace:

```
<?xml version="1.0"?>
<actors xmlns:fictional="http://characters.example.com"
        xmlns="http://people.example.com">
    <actor>
        <name>John Cleese</name>
        <fictional:character>Lancelot</fictional:charact
        <fictional:character>Archie Leach</fictional:cha
    </actor>
    <actor>
        <name>Eric Idle</name>
        <fictional:character>Sir Robin</fictional:charac
        <fictional:character>Gunther</fictional:characte
        <fictional:character>Commander Clement</fictiona
    </actor>
</actors>
```

One way to search and explore this XML example is to manually

add the URI to every tag or attribute in the xpath of a **`find()`** or **`findall()`**:

```
root = fromstring(xml_text)
for actor in root.findall('{http://people.example.com}ac
    name = actor.find('{http://people.example.com}name')
    print(name.text)
    for char in actor.findall('{http://characters.exampl
        print(' |-->', char.text)
```

A better way to search the namespaced XML example is to create a dictionary with your own prefixes and use those in the search functions:

```
ns = {'real_person': 'http://people.example.com',
      'role': 'http://characters.example.com'}

for actor in root.findall('real_person:actor', ns):
    name = actor.find('real_person:name', ns)
    print(name.text)
    for char in actor.findall('role:character', ns):
        print(' |-->', char.text)
```

These two approaches both output:

```
John Cleese
 |--> Lancelot
 |--> Archie Leach
Eric Idle
 |--> Sir Robin
 |--> Gunther
 |--> Commander Clement
```

XPath support

This module provides limited support for XPath expressions [https://www.w3.org/TR/xpath] for locating elements in a tree. The goal is to support a small subset of the abbreviated syntax; a full XPath engine is outside the scope of the module.

Example

Here's an example that demonstrates some of the XPath capabilities of the module. We'll be using the `countrydata` XML document from the Parsing XML section:

```
import xml.etree.ElementTree as ET

root = ET.fromstring(countrydata)

# Top-level elements
root.findall(".")

# All 'neighbor' grand-children of 'country' children of
# elements
root.findall("./country/neighbor")

# Nodes with name='Singapore' that have a 'year' child
root.findall(".//year/..[@name='Singapore']")

# 'year' nodes that are children of nodes with name='Sin
root.findall(".//*[@name='Singapore']/year")

# All 'neighbor' nodes that are the second child of thei
root.findall(".//neighbor[2]")
```

For XML with namespaces, use the usual qualified `{namespace}tag` notation:

```
# All dublin-core "title" tags in the document
root.findall(".//{http://purl.org/dc/elements/1.1/}title
```

Supported XPath syntax

Syntax	Meaning
`tag`	Selects all child elements with the given tag. For example, `spam` selects all child elements named `spam`, and `spam/egg` selects all grandchildren named `egg` in all children named `spam`.
`{namespace}*`	selects all tags in the given namespace, `{*}`

`spam` selects tags named `spam` in any (or no) namespace, and `{}*` only selects tags that are not in a namespace.

Changed in version 3.8: Support for star-wildcards was added.

`*` Selects all child elements, including comments and processing instructions. For example, `*/egg` selects all grandchildren named `egg`.

`.` Selects the current node. This is mostly useful at the beginning of the path, to indicate that it's a relative path.

`//` Selects all subelements, on all levels beneath the current element. For example, `.//egg` selects all `egg` elements in the entire tree.

`..` Selects the parent element. Returns `None` if the path attempts to reach the ancestors of the start element (the element `find` was called on).

`[@attrib]` Selects all elements that have the given attribute.

`[@attrib='value']` Selects all elements for which the given attribute has the given value. The value cannot contain quotes.

`[@attrib!='value']` Selects all elements for which the given attribute does not have the given value. The value cannot contain quotes.

New in version 3.10.

`[tag]` Selects all elements that have a child named `tag`. Only immediate children are supported.

`[.='text']` Selects all elements whose complete text content, including descendants, equals the given `text`.

New in version 3.7.

`[.!='text']` Selects all elements whose complete text content, including descendants, does not equal the given `text`.

New in version 3.10.

`[tag='text']` Selects all elements that have a child named `tag` whose complete text content, including descendants, equals the given `text`.

`[tag!='text']` Selects all elements that have a child named `tag` whose complete text content, including descendants, does not equal the given `text`.

New in version 3.10.

`[position]` Selects all elements that are located at the given position. The position can be either an integer (1 is the first position), the expression `last()` (for the last position), or a position relative to the last position (e.g. `last()-1`).

Predicates (expressions within square brackets) must be preceded

by a tag name, an asterisk, or another predicate. `position` predicates must be preceded by a tag name.

Reference

Functions

xml.etree.ElementTree.canonicalize(*xml_data=None*, *, *out=None*, *from_file=None*, ***options*)

C14N 2.0 [https://www.w3.org/TR/xml-c14n2/] transformation function.

Canonicalization is a way to normalise XML output in a way that allows byte-by-byte comparisons and digital signatures. It reduced the freedom that XML serializers have and instead generates a more constrained XML representation. The main restrictions regard the placement of namespace declarations, the ordering of attributes, and ignorable whitespace.

This function takes an XML data string (*xml_data*) or a file path or file-like object (*from_file*) as input, converts it to the canonical form, and writes it out using the *out* file(-like) object, if provided, or returns it as a text string if not. The output file receives text, not bytes. It should therefore be opened in text mode with `utf-8` encoding.

Typical uses:

```
xml_data = "<root>...</root>"
print(canonicalize(xml_data))

with open("c14n_output.xml", mode='w', encoding='ut
    canonicalize(xml_data, out=out_file)

with open("c14n_output.xml", mode='w', encoding='ut
    canonicalize(from_file="inputfile.xml", out=out
```

The configuration *options* are as follows:

- *with_comments*: set to true to include comments (default: false)
- *strip_text*: set to true to strip whitespace before and after text content
  (default: false)
- *rewrite_prefixes*: set to true to replace namespace prefixes by “n{number}”
  (default: false)
- *qname_aware_tags*: a set of qname aware tag names in which prefixes
  should be replaced in text content (default: empty)
- *qname_aware_attrs*: a set of qname aware attribute names in which prefixes
  should be replaced in text content (default: empty)
- *exclude_attrs*: a set of attribute names that should not be serialised
- *exclude_tags*: a set of tag names that should not be serialised

In the option list above, “a set” refers to any collection or iterable of strings, no ordering is expected.

New in version 3.8.

xml.etree.ElementTree.Comment(*text=None*)

Comment element factory. This factory function creates a special element that will be serialized as an XML comment by the standard serializer. The comment string can be either a bytestring or a Unicode string. *text* is a string containing the comment string. Returns an element instance representing a comment.

Note that **`XMLParser`** skips over comments in the input

instead of creating comment objects for them. An **ElementTree** will only contain comment nodes if they have been inserted into to the tree using one of the **Element** methods.

xml.etree.ElementTree.dump(*elem*)

Writes an element tree or element structure to sys.stdout. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it's written as an ordinary XML file.

elem is an element tree or an individual element.

Changed in version 3.8: The **dump()** function now preserves the attribute order specified by the user.

xml.etree.ElementTree.fromstring(*text*, *parser*=*None*)

Parses an XML section from a string constant. Same as **XML()**. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard **XMLParser** parser is used. Returns an **Element** instance.

xml.etree.ElementTree.fromstringlist(*sequence*, *parser*=*None*)

Parses an XML document from a sequence of string fragments. *sequence* is a list or other sequence containing XML data fragments. *parser* is an optional parser instance. If not given, the standard **XMLParser** parser is used. Returns an **Element** instance.

New in version 3.2.

xml.etree.ElementTree.indent(*tree*, *space*=' ', *level*=*0*)

Appends whitespace to the subtree to indent the tree visually. This can be used to generate pretty-printed XML output. *tree* can be an Element or ElementTree. *space* is the whitespace string that will be inserted for each indentation level, two space characters by default. For indenting partial subtrees

inside of an already indented tree, pass the initial indentation level as *level*.

New in version 3.9.

xml.etree.ElementTree.iselement(*element*)

Check if an object appears to be a valid element object. *element* is an element instance. Return `True` if this is an element object.

xml.etree.ElementTree.iterparse(*source*, *events=None*, *parser=None*)

Parses an XML section into an element tree incrementally, and reports what's going on to the user. *source* is a filename or file object containing XML data. *events* is a sequence of events to report back. The supported events are the strings `"start"`, `"end"`, `"comment"`, `"pi"`, `"start-ns"` and `"end-ns"` (the "ns" events are used to get detailed namespace information). If *events* is omitted, only `"end"` events are reported. *parser* is an optional parser instance. If not given, the standard **`XMLParser`** parser is used. *parser* must be a subclass of **`XMLParser`** and can only use the default **`TreeBuilder`** as a target. Returns an iterator providing `(event, elem)` pairs.

Note that while **`iterparse()`** builds the tree incrementally, it issues blocking reads on *source* (or the file it names). As such, it's unsuitable for applications where blocking reads can't be made. For fully non-blocking parsing, see **`XMLPullParser`**.

Note

`iterparse()` only guarantees that it has seen the ">" character of a starting tag when it emits a "start" event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.

If you need a fully populated element, look for "end"

events instead.

Deprecated since version 3.4: The *parser* argument.

Changed in version 3.8: The `comment` and `pi` events were added.

xml.etree.ElementTree.parse(*source*, *parser*=*None*)

Parses an XML section into an element tree. *source* is a filename or file object containing XML data. *parser* is an optional parser instance. If not given, the standard **`XMLParser`** parser is used. Returns an **`ElementTree`** instance.

xml.etree.ElementTree.ProcessingInstruction(*target*, *text*=*None*)

PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. *target* is a string containing the PI target. *text* is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.

Note that **`XMLParser`** skips over processing instructions in the input instead of creating comment objects for them. An **`ElementTree`** will only contain processing instruction nodes if they have been inserted into to the tree using one of the **`Element`** methods.

xml.etree.ElementTree.register_namespace(*prefix*, *uri*)

Registers a namespace prefix. The registry is global, and any existing mapping for either the given prefix or the namespace URI will be removed. *prefix* is a namespace prefix. *uri* is a namespace uri. Tags and attributes in this namespace will be serialized with the given prefix, if at all possible.

New in version 3.2.

xml.etree.ElementTree.SubElement(*parent*, *tag*, *attrib*=*{}*, ***extra*)

Subelement factory. This function creates an element

instance, and appends it to an existing element.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *parent* is the parent element. *tag* is the subelement name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments. Returns an element instance.

xml.etree.ElementTree.tostring(*element*, *encoding='us-ascii'*, *method='xml'*, ***, *xml_declaration=None*, *default_namespace=None*, *short_empty_elements=True*)

Generates a string representation of an XML element, including all subelements. *element* is an **`Element`** instance. *encoding* [1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`). *xml_declaration*, *default_namespace* and *short_empty_elements* has the same meaning as in **`ElementTree.write()`**. Returns an (optionally) encoded string containing the XML data.

New in version 3.4: The *short_empty_elements* parameter.

New in version 3.8: The *xml_declaration* and *default_namespace* parameters.

Changed in version 3.8: The **`tostring()`** function now preserves the attribute order specified by the user.

xml.etree.ElementTree.tostringlist(*element*, *encoding='us-ascii'*, *method='xml'*, ***, *xml_declaration=None*, *default_namespace=None*, *short_empty_elements=True*)

Generates a string representation of an XML element, including all subelements. *element* is an **`Element`** instance. *encoding* [1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`).

xml_declaration, *default_namespace* and *short_empty_elements* has the same meaning as in **`ElementTree.write()`**. Returns a list of (optionally) encoded strings containing the XML data. It does not guarantee any specific sequence, except that `b"".join(tostringlist(element)) == tostring(element)`.

New in version 3.2.

New in version 3.4: The *short_empty_elements* parameter.

New in version 3.8: The *xml_declaration* and *default_namespace* parameters.

Changed in version 3.8: The **`tostringlist()`** function now preserves the attribute order specified by the user.

xml.etree.ElementTree.XML(*text*, *parser*=*None*)

Parses an XML section from a string constant. This function can be used to embed "XML literals" in Python code. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard **`XMLParser`** parser is used. Returns an **`Element`** instance.

xml.etree.ElementTree.XMLID(*text*, *parser*=*None*)

Parses an XML section from a string constant, and also returns a dictionary which maps from element id:s to elements. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard **`XMLParser`** parser is used. Returns a tuple containing an **`Element`** instance and a dictionary.

XInclude support

This module provides limited support for XInclude directives [https://www.w3.org/TR/xinclude/], via the **`xml.etree.ElementInclude`** helper module. This module can be used to insert subtrees and text strings into element trees, based on information in the tree.

Example

Here's an example that demonstrates use of the XInclude module. To include an XML document in the current document, use the `{http://www.w3.org/2001/XInclude}include` element and set the **parse** attribute to `"xml"`, and use the **href** attribute to specify the document to include.

```
<?xml version="1.0"?>
<document xmlns:xi="http://www.w3.org/2001/XInclude">
  <xi:include href="source.xml" parse="xml" />
</document>
```

By default, the **href** attribute is treated as a file name. You can use custom loaders to override this behaviour. Also note that the standard helper does not support XPointer syntax.

To process this file, load it as usual, and pass the root element to the **`xml.etree.ElementTree`** module:

```
from xml.etree import ElementTree, ElementInclude

tree = ElementTree.parse("document.xml")
root = tree.getroot()

ElementInclude.include(root)
```

The ElementInclude module replaces the `{http://www.w3.org/2001/XInclude}include` element with the root element from the **source.xml** document. The result might look something like this:

```
<document xmlns:xi="http://www.w3.org/2001/XInclude">
  <para>This is a paragraph.</para>
</document>
```

If the **parse** attribute is omitted, it defaults to "xml". The href attribute is required.

To include a text document, use the `{http://www.w3.org/2001/XInclude}include` element, and set the

parse attribute to “text”:

```
<?xml version="1.0"?>
<document xmlns:xi="http://www.w3.org/2001/XInclude">
  Copyright (c) <xi:include href="year.txt" parse="text"
</document>
```

The result might look something like:

```
<document xmlns:xi="http://www.w3.org/2001/XInclude">
  Copyright (c) 2003.
</document>
```

Reference

Functions

xml.etree.ElementInclude.default_loader(*href*, *parse*, *encoding*=*None*)

Default loader. This default loader reads an included resource from disk. *href* is a URL. *parse* is for parse mode either “xml” or “text”. *encoding* is an optional text encoding. If not given, encoding is `utf-8`. Returns the expanded resource. If the parse mode is `"xml"`, this is an ElementTree instance. If the parse mode is “text”, this is a Unicode string. If the loader fails, it can return None or raise an exception.

xml.etree.ElementInclude.include(*elem*, *loader*=*None*, *base_url*=*None*, *max_depth*=*6*)

This function expands XInclude directives. *elem* is the root element. *loader* is an optional resource loader. If omitted, it defaults to **`default_loader()`**. If given, it should be a callable that implements the same interface as **`default_loader()`**. *base_url* is base URL of the original file, to resolve relative include file references. *max_depth* is the maximum number of recursive inclusions. Limited to reduce the risk of malicious content explosion. Pass a negative value to disable the limitation.

Returns the expanded resource. If the parse mode is `"xml"`, this is an ElementTree instance. If the parse mode is “text”, this is a Unicode string. If the loader fails, it can return None or raise an exception.

New in version 3.9: The *base_url* and *max_depth* parameters.

Element Objects

class xml.etree.ElementTree.Element(*tag*, *attrib*=*{}*, ***extra*)

Element class. This class defines the Element interface, and provides a reference implementation of this interface.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *tag* is the element name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments.

tag

A string identifying what kind of data this element represents (the element type, in other words).

text
tail

These attributes can be used to hold additional data associated with the element. Their values are usually strings but may be any application-specific object. If the element is created from an XML file, the *text* attribute holds either the text between the element’s start tag and its first child or end tag, or `None`, and the *tail* attribute holds either the text between the element’s end tag and the next tag, or `None`. For the XML data

```
<a><b>1<c>2<d/>3</c></b>4</a>
```

the *a* element has `None` for both *text* and *tail* attributes, the *b* element has *text* `"1"` and *tail* `"4"`, the *c* element has *text* `"2"` and *tail* `None`, and the *d*

element has *text* `None` and *tail* `"3"`.

To collect the inner text of an element, see **`itertext()`**, for example `"".join(element.itertext())`.

Applications may store arbitrary objects in these attributes.

attrib

A dictionary containing the element's attributes. Note that while the *attrib* value is always a real mutable Python dictionary, an ElementTree implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

clear()

Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to `None`.

get(*key*, *default*=*None*)

Gets the element attribute named *key*.

Returns the attribute value, or *default* if the attribute was not found.

items()

Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

keys()

Returns the elements attribute names as a list. The names are returned in an arbitrary order.

set(*key*, *value*)

Set the attribute *key* on the element to *value*.

The following methods work on the element's children (subelements).

append(*subelement*)

Adds the element *subelement* to the end of this element's internal list of subelements. Raises **`TypeError`** if *subelement* is not an **`Element`**.

extend(*subelements*)

Appends *subelements* from a sequence object with zero or more elements. Raises **`TypeError`** if a subelement is not an **`Element`**.

New in version 3.2.

find(*match*, *namespaces=None*)

Finds the first subelement matching *match*. *match* may be a tag name or a path. Returns an element instance or `None`. *namespaces* is an optional mapping from namespace prefix to full name. Pass `''` as prefix to move all unprefixed tag names in the expression into the given namespace.

findall(*match*, *namespaces=None*)

Finds all matching subelements, by tag name or path. Returns a list containing all matching elements in document order. *namespaces* is an optional mapping from namespace prefix to full name. Pass `''` as prefix to move all unprefixed tag names in the expression into the given namespace.

findtext(*match*, *default*=*None*, *namespaces*=*None*)

Finds text for the first subelement matching *match*. *match* may be a tag name or a path. Returns the text content of the first matching element, or *default* if no element was found. Note that if the matching element has no text content an empty string is returned. *namespaces* is an optional mapping from namespace prefix to full name. Pass `''` as prefix to move all unprefixed tag names in the expression into the given namespace.

insert(*index*, *subelement*)

Inserts *subelement* at the given position in this element. Raises **`TypeError`** if *subelement* is not an **`Element`**.

iter(*tag*=*None*)

Creates a tree iterator with the current element as the root. The iterator iterates over this element and all elements below it, in document (depth first) order. If *tag* is not `None` or `'*'`, only elements whose tag equals *tag* are returned from the iterator. If the tree structure is modified during iteration, the result is undefined.

New in version 3.2.

iterfind(*match*, *namespaces*=*None*)

Finds all matching subelements, by tag name or path. Returns an iterable yielding all matching elements in document order. *namespaces* is an optional mapping from namespace prefix to full name.

New in version 3.2.

itertext()

Creates a text iterator. The iterator loops over this element and all subelements, in document order, and returns all inner text.

New in version 3.2.

makeelement(*tag*, *attrib*)

Creates a new element object of the same type as this element. Do not call this method, use the **SubElement()** factory function instead.

remove(*subelement*)

Removes *subelement* from the element. Unlike the find* methods this method compares elements based on the instance identity, not on tag value or contents.

Element objects also support the following sequence type methods for working with subelements: **__delitem__()**, **__getitem__()**, **__setitem__()**, **__len__()**.

Caution: Elements with no subelements will test as `False`. This behavior will change in future versions. Use specific `len(elem)` or `elem is None` test instead.

```
element = root.find('foo')

if not element:  # careful!
    print("element not found, or element has no sub

if element is None:
    print("element not found")
```

Prior to Python 3.8, the serialisation order of the XML attributes of elements was artificially made predictable by sorting the attributes by their name. Based on the now guaranteed ordering of dicts, this arbitrary reordering was removed in Python 3.8 to preserve the order in which attributes were originally parsed or created by user code.

In general, user code should try not to depend on a specific ordering of attributes, given that the XML Information Set [https://www.w3.org/TR/xml-infoset/] explicitly excludes the attribute order from conveying information. Code should be

prepared to deal with any ordering on input. In cases where deterministic XML output is required, e.g. for cryptographic signing or test data sets, canonical serialisation is available with the **`canonicalize()`** function.

In cases where canonical output is not applicable but a specific attribute order is still desirable on output, code should aim for creating the attributes directly in the desired order, to avoid perceptual mismatches for readers of the code. In cases where this is difficult to achieve, a recipe like the following can be applied prior to serialisation to enforce an order independently from the Element creation:

```
def reorder_attributes(root):
    for el in root.iter():
        attrib = el.attrib
        if len(attrib) > 1:
            # adjust attribute order, e.g. by sorti
            attribs = sorted(attrib.items())
            attrib.clear()
            attrib.update(attribs)
```

ElementTree Objects

class xml.etree.ElementTree.ElementTree(*element=None*, *file=None*)

ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

element is the root element. The tree is initialized with the contents of the XML *file* if given.

_setroot(*element*)

Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. *element* is an element instance.

find(*match*, *namespaces*=*None*)

Same as **`Element.find()`**, starting at the root of the tree.

findall(*match*, *namespaces*=*None*)

Same as **`Element.findall()`**, starting at the root of the tree.

findtext(*match*, *default*=*None*, *namespaces*=*None*)

Same as **`Element.findtext()`**, starting at the root of the tree.

getroot()

Returns the root element for this tree.

iter(*tag*=*None*)

Creates and returns a tree iterator for the root element. The iterator loops over all elements in this tree, in section order. *tag* is the tag to look for (default is to return all elements).

iterfind(*match*, *namespaces*=*None*)

Same as **`Element.iterfind()`**, starting at the root of the tree.

New in version 3.2.

parse(*source*, *parser*=*None*)

Loads an external XML section into this element tree. *source* is a file name or file object. *parser* is an optional parser instance. If not given, the standard **`XMLParser`** parser is used. Returns the section root element.

write(*file*, *encoding*='us-ascii', *xml_declaration*=*None*, *default_namespace*=*None*, *method*='xml', ***, *short_empty_elements*=*True*)

Writes the element tree to a file, as XML. *file* is a file name, or a file object opened for writing. *encoding* 1 is the output encoding (default is US-ASCII). *xml_declaration* controls if an XML declaration should be added to the file. Use `False` for never, `True` for always, `None` for only if not US-ASCII or UTF-8 or Unicode (default is `None`). *default_namespace* sets the default XML namespace (for "xmlns"). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`). The keyword-only *short_empty_elements* parameter controls the formatting of elements that contain no content. If `True` (the default), they are emitted as a single self-closed tag, otherwise they are emitted as a pair of start/end tags.

The output is either a string (**`str`**) or binary (**`bytes`**). This is controlled by the *encoding* argument. If *encoding* is `"unicode"`, the output is a string; otherwise, it's binary. Note that this may conflict with the type of *file* if it's an open file object; make sure you do not try to write a string to a binary stream and vice versa.

New in version 3.4: The *short_empty_elements* parameter.

Changed in version 3.8: The **`write()`** method now preserves the attribute order specified by the user.

This is the XML file that is going to be manipulated:

```
<html>
    <head>
        <title>Example page</title>
    </head>
    <body>
        <p>Moved to <a href="http://example.org/">exampl
        or <a href="http://example.com/">example.com</a>
    </body>
</html>
```

Example of changing the attribute "target" of every link in first

paragraph:

```
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
>>> tree.parse("index.xhtml")
<Element 'html' at 0xb77e6fac>
>>> p = tree.find("body/p")     # Finds first occurrence
>>> p
<Element 'p' at 0xb77ec26c>
>>> links = list(p.iter("a"))   # Returns list of all li
>>> links
[<Element 'a' at 0xb77ec2ac>, <Element 'a' at 0xb77ec1cc
>>> for i in links:             # Iterates through all f
...     i.attrib["target"] = "blank"
>>> tree.write("output.xhtml")
```

QName Objects

class xml.etree.ElementTree.QName(*text_or_uri*, *tag=None*)

QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. *text_or_uri* is a string containing the QName value, in the form {uri}local, or, if the tag argument is given, the URI part of a QName. If *tag* is given, the first argument is interpreted as a URI, and this argument is interpreted as a local name. `QName` instances are opaque.

TreeBuilder Objects

class xml.etree.ElementTree.TreeBuilder(*element_factory=None*, ***, *comment_factory=None*, *pi_factory=None*, *insert_comments=False*, *insert_pis=False*)

Generic element structure builder. This builder converts a sequence of start, data, end, comment and pi method calls to a well-formed element structure. You can use this class to build an element structure using a custom XML parser, or a parser for some other XML-like format.

element_factory, when given, must be a callable accepting two positional arguments: a tag and a dict of attributes. It is expected to return a new element instance.

The *comment_factory* and *pi_factory* functions, when given, should behave like the `Comment()` and `ProcessingInstruction()` functions to create comments and processing instructions. When not given, the default factories will be used. When *insert_comments* and/or *insert_pis* is true, comments/pis will be inserted into the tree if they appear within the root element (but not outside of it).

close()

Flushes the builder buffers, and returns the toplevel document element. Returns an `Element` instance.

data(*data*)

Adds text to the current element. *data* is a string. This should be either a bytestring, or a Unicode string.

end(*tag*)

Closes the current element. *tag* is the element name. Returns the closed element.

start(*tag*, *attrs*)

Opens a new element. *tag* is the element name. *attrs* is a dictionary containing element attributes. Returns the opened element.

comment(*text*)

Creates a comment with the given *text*. If `insert_comments` is true, this will also add it to the tree.

New in version 3.8.

pi(*target*, *text*)

Creates a comment with the given *target* name and *text*. If `insert_pis` is true, this will also add it to the tree.

New in version 3.8.

In addition, a custom **`TreeBuilder`** object can provide the following methods:

doctype(*name*, *pubid*, *system*)

Handles a doctype declaration. *name* is the doctype name. *pubid* is the public identifier. *system* is the system identifier. This method does not exist on the default **`TreeBuilder`** class.

New in version 3.2.

start_ns(*prefix*, *uri*)

Is called whenever the parser encounters a new namespace declaration, before the `start()` callback for the opening element that defines it. *prefix* is `''` for the default namespace and the declared namespace prefix name otherwise. *uri* is the namespace URI.

New in version 3.8.

end_ns(*prefix*)

Is called after the `end()` callback of an element that declared a namespace prefix mapping, with the name of the *prefix* that went out of scope.

New in version 3.8.

class xml.etree.ElementTree.C14NWriterTarget(*write*, ***, *with_comments=False*, *strip_text=False*, *rewrite_prefixes=False*, *qname_aware_tags=None*, *qname_aware_attrs=None*, *exclude_attrs=None*, *exclude_tags=None*)

A C14N 2.0 [https://www.w3.org/TR/xml-c14n2/] writer. Arguments are the same as for the **`canonicalize()`**

function. This class does not build a tree but translates the callback events directly into a serialised form using the *write* function.

New in version 3.8.

XMLParser Objects

class xml.etree.ElementTree.XMLParser(*, *target*=*None*, *encoding*=*None*)

This class is the low-level building block of the module. It uses **`xml.parsers.expat`** for efficient, event-based parsing of XML. It can be fed XML data incrementally with the **`feed()`** method, and parsing events are translated to a push API - by invoking callbacks on the *target* object. If *target* is omitted, the standard **`TreeBuilder`** is used. If *encoding* 1 is given, the value overrides the encoding specified in the XML file.

Changed in version 3.8: Parameters are now keyword-only. The *html* argument no longer supported.

close()

Finishes feeding data to the parser. Returns the result of calling the `close()` method of the *target* passed during construction; by default, this is the toplevel document element.

feed(*data*)

Feeds data to the parser. *data* is encoded data.

`XMLParser.feed()` calls *target*'s `start(tag, attrs_dict)` method for each opening tag, its `end(tag)` method for each closing tag, and data is processed by method `data(data)`. For further supported callback methods, see the **`TreeBuilder`** class. **`XMLParser.close()`** calls *target*'s method `close()`. **`XMLParser`** can be used not only for building a tree structure. This is an example of counting the

maximum depth of an XML file:

```
>>> from xml.etree.ElementTree import XMLParser
>>> class MaxDepth:                     # The targe
...     maxDepth = 0
...     depth = 0
...     def start(self, tag, attrib):   # Called fo
...         self.depth += 1
...         if self.depth > self.maxDepth:
...             self.maxDepth = self.depth
...     def end(self, tag):             # Called fo
...         self.depth -= 1
...     def data(self, data):
...         pass            # We do not need to do
...     def close(self):    # Called when all data
...         return self.maxDepth
...
>>> target = MaxDepth()
>>> parser = XMLParser(target=target)
>>> exampleXml = """
... <a>
...   <b>
...   </b>
...   <b>
...     <c>
...       <d>
...       </d>
...     </c>
...   </b>
... </a>"""
>>> parser.feed(exampleXml)
>>> parser.close()
4
```

XMLPullParser Objects

class xml.etree.ElementTree.XMLPullParser(*events=None*)

A pull parser suitable for non-blocking applications. Its input-

side API is similar to that of **XMLParser**, but instead of pushing calls to a callback target, **XMLPullParser** collects an internal list of parsing events and lets the user read from it. *events* is a sequence of events to report back. The supported events are the strings `"start"`, `"end"`, `"comment"`, `"pi"`, `"start-ns"` and `"end-ns"` (the "ns" events are used to get detailed namespace information). If *events* is omitted, only `"end"` events are reported.

feed(*data*)

Feed the given bytes data to the parser.

close()

Signal the parser that the data stream is terminated. Unlike **XMLParser.close()**, this method always returns **None**. Any events not yet retrieved when the parser is closed can still be read with **read_events()**.

read_events()

Return an iterator over the events which have been encountered in the data fed to the parser. The iterator yields `(event, elem)` pairs, where *event* is a string representing the type of event (e.g. `"end"`) and *elem* is the encountered **Element** object, or other context value as follows.

- `start`, `end`: the current Element.
- `comment`, `pi`: the current comment / processing instruction
- `start-ns`: a tuple `(prefix, uri)` naming the declared namespace mapping.
- `end-ns`: **None** (this may change in a future version)

Events provided in a previous call to **read_events()** will not be yielded again. Events are consumed from the internal queue only when they are retrieved from the iterator, so multiple readers iterating in parallel

over iterators obtained from **read_events()** will have unpredictable results.

Note

XMLPullParser only guarantees that it has seen the “>” character of a starting tag when it emits a “start” event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.

If you need a fully populated element, look for “end” events instead.

New in version 3.4.

Changed in version 3.8: The `comment` and `pi` events were added.

Exceptions

class xml.etree.ElementTree.ParseError

XML parse error, raised by the various parsing methods in this module when parsing fails. The string representation of an instance of this exception will contain a user-friendly error message. In addition, it will have the following attributes available:

code

A numeric error code from the expat parser. See the documentation of **xml.parsers.expat** for the list of error codes and their meanings.

position

A tuple of *line*, *column* numbers, specifying where the error occurred.

Footnotes

1(*1*,*2*,*3*,*4*)

The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

`xml.dom` — The Document Object Model API

Source code: Lib/xml/dom/__init__.py [https://github.com/python/cpython/tree/3.11/Lib/xml/dom/__init__.py]

The Document Object Model, or “DOM,” is a cross-language API from the World Wide Web Consortium (W3C) for accessing and modifying XML documents. A DOM implementation presents an XML document as a tree structure, or allows client code to build such a structure from scratch. It then gives access to the structure through a set of objects which provided well-known interfaces.

The DOM is extremely useful for random-access applications. SAX only allows you a view of one bit of the document at a time. If you are looking at one SAX element, you have no access to another. If you are looking at a text node, you have no access to a containing element. When you write a SAX application, you need to keep track of your program’s position in the document somewhere in your own code. SAX does not do it for you. Also, if you need to look ahead in the XML document, you are just out of luck.

Some applications are simply impossible in an event driven model with no access to a tree. Of course you could build some sort of tree yourself in SAX events, but the DOM allows you to avoid writing that code. The DOM is a standard tree representation for XML data.

The Document Object Model is being defined by the W3C in stages, or “levels” in their terminology. The Python mapping of the API is substantially based on the DOM Level 2 recommendation.

DOM applications typically start by parsing some XML into a DOM. How this is accomplished is not covered at all by DOM Level 1, and Level 2 provides only limited improvements: There is a **`DOMImplementation`** object class which provides access to

Document creation methods, but no way to access an XML reader/parser/Document builder in an implementation-independent way. There is also no well-defined way to access these methods without an existing **Document** object. In Python, each DOM implementation will provide a function **getDOMImplementation()**. DOM Level 3 adds a Load/Store specification, which defines an interface to the reader, but this is not yet available in the Python standard library.

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification; this portion of the reference manual describes the interpretation of the specification in Python.

The specification provided by the W3C defines the DOM API for Java, ECMAScript, and OMG IDL. The Python mapping defined here is based in large part on the IDL version of the specification, but strict compliance is not required (though implementations are free to support the strict mapping from IDL). See section Conformance for a detailed discussion of mapping requirements.

Document Object Model (DOM) Level 1 Specification **[https://www.w3.org/TR/REC-DOM-Level-1/]**
: The W3C recommendation for the DOM supported by **xml.dom.minidom**.

Python Language Mapping Specification **[https://www.omg.org/spec/PYTH/1.2/PDF]**
: This specifies the mapping from OMG IDL to Python.

Module Contents

The **xml.dom** contains the following functions:

xml.dom.registerDOMImplementation(*name*, *factory*)

Register the *factory* function with the name *name*. The factory function should return an object which implements the **DOMImplementation** interface. The factory function can return the same object every time, or a new one for each call, as appropriate for the specific implementation (e.g. if that implementation supports some customization).

xml.dom.getDOMImplementation(*name* = *None*, *features* = *()*)

Return a suitable DOM implementation. The *name* is either well-known, the module name of a DOM implementation, or `None`. If it is not `None`, imports the corresponding module and returns a **DOMImplementation** object if the import succeeds. If no name is given, and if the environment variable **PYTHON_DOM** is set, this variable is used to find the implementation.

If name is not given, this examines the available implementations to find one with the required feature set. If no implementation can be found, raise an **ImportError**. The features list must be a sequence of `(feature, version)` pairs which are passed to the **hasFeature()** method on available **DOMImplementation** objects.

Some convenience constants are also provided:

xml.dom.EMPTY_NAMESPACE

The value used to indicate that no namespace is associated with a node in the DOM. This is typically found as the **namespaceURI** of a node, or used as the *namespaceURI* parameter to a namespaces-specific method.

xml.dom.XML_NAMESPACE

The namespace URI associated with the reserved prefix `xml`, as defined by Namespaces in XML [https://www.w3.org/TR/REC-xml-names/] (section 4).

xml.dom.XMLNS_NAMESPACE

The namespace URI for namespace declarations, as defined by Document Object Model (DOM) Level 2 Core Specification [https://www.w3.org/TR/DOM-Level-2-Core/core.html] (section 1.1.8).

xml.dom.XHTML_NAMESPACE

The URI of the XHTML namespace as defined by XHTML 1.0: The Extensible HyperText Markup Language [https://www.w3.org/TR/xhtml1/] (section 3.1.1).

In addition, `xml.dom` contains a base `Node` class and the DOM exception classes. The `Node` class provided by this module does not implement any of the methods or attributes defined by the DOM specification; concrete DOM implementations must provide those. The `Node` class provided as part of this module does provide the constants used for the `nodeType` attribute on concrete `Node` objects; they are located within the class rather than at the module level to conform with the DOM specifications.

Objects in the DOM

The definitive documentation for the DOM is the DOM specification from the W3C.

Note that DOM attributes may also be manipulated as nodes instead of as simple strings. It is fairly rare that you must do this, however, so this usage is not yet documented.

Interface	Purpose
DOMImplementation Objects	Interface to the underlying implementation.
Node Objects	Base interface for most objects in a document.
NodeList Objects	Interface for a sequence of nodes.
DocumentType Objects	Information about the declarations needed to process a document.
Document Objects	Object which represents an entire document.
Element Objects	Element nodes in the document hierarchy.
Attr Objects	Attribute value nodes on element nodes.
Comment Objects	Representation of comments in the source document.
Text and CDATASection Objects	Nodes containing textual content from the document.

Processing instructions represent

An additional section describes the exceptions defined for working with the DOM in Python.

DOMImplementation Objects

The **DOMImplementation** interface provides a way for applications to determine the availability of particular features in the DOM they are using. DOM Level 2 added the ability to create new **Document** and **DocumentType** objects using the **DOMImplementation** as well.

DOMImplementation.hasFeature(*feature*, *version*)

Return `True` if the feature identified by the pair of strings *feature* and *version* is implemented.

DOMImplementation.createDocument(*namespaceUri*, *qualifiedName*, *doctype*)

Return a new **Document** object (the root of the DOM), with a child **Element** object having the given *namespaceUri* and *qualifiedName*. The *doctype* must be a **DocumentType** object created by **createDocumentType()**, or `None`. In the Python DOM API, the first two arguments can also be `None` in order to indicate that no **Element** child is to be created.

DOMImplementation.createDocumentType(*qualifiedName*, *publicId*, *systemId*)

Return a new **DocumentType** object that encapsulates the given *qualifiedName*, *publicId*, and *systemId* strings, representing the information contained in an XML document type declaration.

Node Objects

All of the components of an XML document are subclasses of **Node**.

Node.nodeType

An integer representing the node type. Symbolic constants for the types are on the **Node** object: **ELEMENT_NODE**, **ATTRIBUTE_NODE**, **TEXT_NODE**, **CDATA_SECTION_NODE**, **ENTITY_NODE**, **PROCESSING_INSTRUCTION_NODE**, **COMMENT_NODE**, **DOCUMENT_NODE**, **DOCUMENT_TYPE_NODE**, **NOTATION_NODE**. This is a read-only attribute.

Node.parentNode

The parent of the current node, or `None` for the document node. The value is always a **Node** object or `None`. For **Element** nodes, this will be the parent element, except for the root element, in which case it will be the **Document** object. For **Attr** nodes, this is always `None`. This is a read-only attribute.

Node.attributes

A **NamedNodeMap** of attribute objects. Only elements have actual values for this; others provide `None` for this attribute. This is a read-only attribute.

Node.previousSibling

The node that immediately precedes this one with the same parent. For instance the element with an end-tag that comes just before the *self* element's start-tag. Of course, XML documents are made up of more than just elements so the previous sibling could be text, a comment, or something else. If this node is the first child of the parent, this attribute will be `None`. This is a read-only attribute.

Node.nextSibling

The node that immediately follows this one with the same parent. See also **previousSibling**. If this is the last child of the parent, this attribute will be `None`. This is a read-only attribute.

Node.childNodes

A list of nodes contained within this node. This is a read-only

attribute.

Node.firstChild

The first child of the node, if there are any, or `None`. This is a read-only attribute.

Node.lastChild

The last child of the node, if there are any, or `None`. This is a read-only attribute.

Node.localName

The part of the **`tagName`** following the colon if there is one, else the entire **`tagName`**. The value is a string.

Node.prefix

The part of the **`tagName`** preceding the colon if there is one, else the empty string. The value is a string, or `None`.

Node.namespaceURI

The namespace associated with the element name. This will be a string or `None`. This is a read-only attribute.

Node.nodeName

This has a different meaning for each node type; see the DOM specification for details. You can always get the information you would get here from another property such as the **`tagName`** property for elements or the **`name`** property for attributes. For all node types, the value of this attribute will be either a string or `None`. This is a read-only attribute.

Node.nodeValue

This has a different meaning for each node type; see the DOM specification for details. The situation is similar to that with **`nodeName`**. The value is a string or `None`.

Node.hasAttributes()

Return `True` if the node has any attributes.

Node.hasChildNodes()

Return `True` if the node has any child nodes.

Node.isSameNode(*other*)

Return `True` if *other* refers to the same node as this node. This is especially useful for DOM implementations which use any sort of proxy architecture (because more than one object can refer to the same node).

Note

This is based on a proposed DOM Level 3 API which is still in the "working draft" stage, but this particular interface appears uncontroversial. Changes from the W3C will not necessarily affect this method in the Python DOM interface (though any new W3C API for this would also be supported).

Node.appendChild(*newChild*)

Add a new child node to this node at the end of the list of children, returning *newChild*. If the node was already in the tree, it is removed first.

Node.insertBefore(*newChild*, *refChild*)

Insert a new child node before an existing child. It must be the case that *refChild* is a child of this node; if not, **`ValueError`** is raised. *newChild* is returned. If *refChild* is `None`, it inserts *newChild* at the end of the children's list.

Node.removeChild(*oldChild*)

Remove a child node. *oldChild* must be a child of this node; if not, **`ValueError`** is raised. *oldChild* is returned on success. If *oldChild* will not be used further, its **`unlink()`** method should be called.

Node.replaceChild(*newChild*, *oldChild*)

Replace an existing node with a new node. It must be the case that *oldChild* is a child of this node; if not, **ValueError** is raised.

Node.normalize()

Join adjacent text nodes so that all stretches of text are stored as single **Text** instances. This simplifies processing text from a DOM tree for many applications.

Node.cloneNode(*deep*)

Clone this node. Setting *deep* means to clone all child nodes as well. This returns the clone.

NodeList Objects

A **NodeList** represents a sequence of nodes. These objects are used in two ways in the DOM Core recommendation: an **Element** object provides one as its list of child nodes, and the **getElementsByTagName()** and **getElementsByTagNameNS()** methods of **Node** return objects with this interface to represent query results.

The DOM Level 2 recommendation defines one method and one attribute for these objects:

NodeList.item(*i*)

Return the *i*'th item from the sequence, if there is one, or `None`. The index *i* is not allowed to be less than zero or greater than or equal to the length of the sequence.

NodeList.length

The number of nodes in the sequence.

In addition, the Python DOM interface requires that some additional support is provided to allow **NodeList** objects to be used as Python sequences. All **NodeList** implementations must include support for **__len__()** and **__getitem__()**; this allows iteration over the **NodeList** in **for** statements and proper

support for the **len()** built-in function.

If a DOM implementation supports modification of the document, the **NodeList** implementation must also support the **__setitem__()** and **__delitem__()** methods.

DocumentType Objects

Information about the notations and entities declared by a document (including the external subset if the parser uses it and can provide the information) is available from a **DocumentType** object. The **DocumentType** for a document is available from the **Document** object's **doctype** attribute; if there is no `DOCTYPE` declaration for the document, the document's **doctype** attribute will be set to `None` instead of an instance of this interface.

DocumentType is a specialization of **Node**, and adds the following attributes:

DocumentType.publicId

> The public identifier for the external subset of the document type definition. This will be a string or `None`.

DocumentType.systemId

> The system identifier for the external subset of the document type definition. This will be a URI as a string, or `None`.

DocumentType.internalSubset

> A string giving the complete internal subset from the document. This does not include the brackets which enclose the subset. If the document has no internal subset, this should be `None`.

DocumentType.name

> The name of the root element as given in the `DOCTYPE` declaration, if present.

DocumentType.entities

> This is a **NamedNodeMap** giving the definitions of external

entities. For entity names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be `None` if the information is not provided by the parser, or if no entities are defined.

DocumentType.notations

This is a **`NamedNodeMap`** giving the definitions of notations. For notation names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be `None` if the information is not provided by the parser, or if no notations are defined.

Document Objects

A **`Document`** represents an entire XML document, including its constituent elements, attributes, processing instructions, comments etc. Remember that it inherits properties from **`Node`**.

Document.documentElement

The one and only root element of the document.

Document.createElement(*tagName*)

Create and return a new element node. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as **`insertBefore()`** or **`appendChild()`**.

Document.createElementNS(*namespaceURI*, *tagName*)

Create and return a new element with a namespace. The *tagName* may have a prefix. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as **`insertBefore()`** or **`appendChild()`**.

Document.createTextNode(*data*)

Create and return a text node containing the data passed as a parameter. As with the other creation methods, this one does

not insert the node into the tree.

Document.createComment(*data*)

Create and return a comment node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

Document.createProcessingInstruction(*target*, *data*)

Create and return a processing instruction node containing the *target* and *data* passed as parameters. As with the other creation methods, this one does not insert the node into the tree.

Document.createAttribute(*name*)

Create and return an attribute node. This method does not associate the attribute node with any particular element. You must use **`setAttributeNode()`** on the appropriate **`Element`** object to use the newly created attribute instance.

Document.createAttributeNS(*namespaceURI*, *qualifiedName*)

Create and return an attribute node with a namespace. The *tagName* may have a prefix. This method does not associate the attribute node with any particular element. You must use **`setAttributeNode()`** on the appropriate **`Element`** object to use the newly created attribute instance.

Document.getElementsByTagName(*tagName*)

Search for all descendants (direct children, children's children, etc.) with a particular element type name.

Document.getElementsByTagNameNS(*namespaceURI*, *localName*)

Search for all descendants (direct children, children's children, etc.) with a particular namespace URI and localname. The localname is the part of the namespace after the prefix.

Element Objects

`Element` is a subclass of **`Node`**, so inherits all the attributes of that class.

Element.tagName

The element type name. In a namespace-using document it may have colons in it. The value is a string.

Element.getElementsByTagName(*tagName*)

Same as equivalent method in the **`Document`** class.

Element.getElementsByTagNameNS(*namespaceURI*, *localName*)

Same as equivalent method in the **`Document`** class.

Element.hasAttribute(*name*)

Return `True` if the element has an attribute named by *name*.

Element.hasAttributeNS(*namespaceURI*, *localName*)

Return `True` if the element has an attribute named by *namespaceURI* and *localName*.

Element.getAttribute(*name*)

Return the value of the attribute named by *name* as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

Element.getAttributeNode(*attrname*)

Return the **`Attr`** node for the attribute named by *attrname*.

Element.getAttributeNS(*namespaceURI*, *localName*)

Return the value of the attribute named by *namespaceURI* and *localName* as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

Element.getAttributeNodeNS(*namespaceURI*, *localName*)

Return an attribute value as a node, given a *namespaceURI* and *localName*.

Element.removeAttribute(*name*)

Remove an attribute by name. If there is no matching attribute, a **NotFoundErr** is raised.

Element.removeAttributeNode(*oldAttr*)

Remove and return *oldAttr* from the attribute list, if present. If *oldAttr* is not present, **NotFoundErr** is raised.

Element.removeAttributeNS(*namespaceURI*, *localName*)

Remove an attribute by name. Note that it uses a localName, not a qname. No exception is raised if there is no matching attribute.

Element.setAttribute(*name*, *value*)

Set an attribute value from a string.

Element.setAttributeNode(*newAttr*)

Add a new attribute node to the element, replacing an existing attribute if necessary if the **name** attribute matches. If a replacement occurs, the old attribute node will be returned. If *newAttr* is already in use, **InuseAttributeErr** will be raised.

Element.setAttributeNodeNS(*newAttr*)

Add a new attribute node to the element, replacing an existing attribute if necessary if the **namespaceURI** and **localName** attributes match. If a replacement occurs, the old attribute node will be returned. If *newAttr* is already in use, **InuseAttributeErr** will be raised.

Element.setAttributeNS(*namespaceURI*, *qname*, *value*)

Set an attribute value from a string, given a *namespaceURI*

and a *qname*. Note that a qname is the whole attribute name. This is different than above.

Attr Objects

`Attr` inherits from **`Node`**, so inherits all its attributes.

Attr.name
: The attribute name. In a namespace-using document it may include a colon.

Attr.localName
: The part of the name following the colon if there is one, else the entire name. This is a read-only attribute.

Attr.prefix
: The part of the name preceding the colon if there is one, else the empty string.

Attr.value
: The text value of the attribute. This is a synonym for the **`nodeValue`** attribute.

NamedNodeMap Objects

`NamedNodeMap` does *not* inherit from **`Node`**.

NamedNodeMap.length
: The length of the attribute list.

NamedNodeMap.item(*index*)
: Return an attribute with a particular index. The order you get the attributes in is arbitrary but will be consistent for the life of a DOM. Each item is an attribute node. Get its value with the **`value`** attribute.

There are also experimental methods that give this class more

mapping behavior. You can use them or you can use the standardized **getAttribute*()** family of methods on the **Element** objects.

Comment Objects

Comment represents a comment in the XML document. It is a subclass of **Node**, but cannot have child nodes.

Comment.data

> The content of the comment as a string. The attribute contains all characters between the leading <!-- and trailing -->, but does not include them.

Text and CDATASection Objects

The **Text** interface represents text in the XML document. If the parser and DOM implementation support the DOM's XML extension, portions of the text enclosed in CDATA marked sections are stored in **CDATASection** objects. These two interfaces are identical, but provide different values for the **nodeType** attribute.

These interfaces extend the **Node** interface. They cannot have child nodes.

Text.data

> The content of the text node as a string.

Note

The use of a **CDATASection** node does not indicate that the node represents a complete CDATA marked section, only that the content of the node was part of a CDATA section. A single CDATA section may be represented by more than one node in the document tree. There is no way to determine whether two adjacent **CDATASection** nodes represent different CDATA marked sections.

ProcessingInstruction Objects

Represents a processing instruction in the XML document; this inherits from the **Node** interface and cannot have child nodes.

ProcessingInstruction.target

> The content of the processing instruction up to the first whitespace character. This is a read-only attribute.

ProcessingInstruction.data

> The content of the processing instruction following the first whitespace character.

Exceptions

The DOM Level 2 recommendation defines a single exception, **DOMException**, and a number of constants that allow applications to determine what sort of error occurred. **DOMException** instances carry a **code** attribute that provides the appropriate value for the specific exception.

The Python DOM interface provides the constants, but also expands the set of exceptions so that a specific exception exists for each of the exception codes defined by the DOM. The implementations must raise the appropriate specific exception, each of which carries the appropriate value for the **code** attribute.

exception xml.dom.DOMException

> Base exception class used for all specific DOM exceptions. This exception class cannot be directly instantiated.

exception xml.dom.DomstringSizeErr

> Raised when a specified range of text does not fit into a string. This is not known to be used in the Python DOM implementations, but may be received from DOM implementations not written in Python.

exception xml.dom.HierarchyRequestErr

Raised when an attempt is made to insert a node where the node type is not allowed.

exception xml.dom.IndexSizeErr

Raised when an index or size parameter to a method is negative or exceeds the allowed values.

exception xml.dom.InuseAttributeErr

Raised when an attempt is made to insert an **`Attr`** node that is already present elsewhere in the document.

exception xml.dom.InvalidAccessErr

Raised if a parameter or an operation is not supported on the underlying object.

exception xml.dom.InvalidCharacterErr

This exception is raised when a string parameter contains a character that is not permitted in the context it's being used in by the XML 1.0 recommendation. For example, attempting to create an **`Element`** node with a space in the element type name will cause this error to be raised.

exception xml.dom.InvalidModificationErr

Raised when an attempt is made to modify the type of a node.

exception xml.dom.InvalidStateErr

Raised when an attempt is made to use an object that is not defined or is no longer usable.

exception xml.dom.NamespaceErr

If an attempt is made to change any object in a way that is not permitted with regard to the Namespaces in XML [https://www.w3.org/TR/REC-xml-names/] recommendation, this exception is raised.

exception xml.dom.NotFoundErr

Exception when a node does not exist in the referenced

context. For example, **`NamedNodeMap.removeNamedItem()`** will raise this if the node passed in does not exist in the map.

exception xml.dom.NotSupportedErr

Raised when the implementation does not support the requested type of object or operation.

exception xml.dom.NoDataAllowedErr

This is raised if data is specified for a node which does not support data.

exception xml.dom.NoModificationAllowedErr

Raised on attempts to modify an object where modifications are not allowed (such as for read-only nodes).

exception xml.dom.SyntaxErr

Raised when an invalid or illegal string is specified.

exception xml.dom.WrongDocumentErr

Raised when a node is inserted in a different document than it currently belongs to, and the implementation does not support migrating the node from one document to the other.

The exception codes defined in the DOM recommendation map to the exceptions described above according to this table:

Exception
DOMSTRING_SIZE_ERR
HIERARCHY_REQUEST_ERR
INDEX_SIZE_ERR
INUSE_ATTRIBUTE_ERR
INVALID_ACCESS_ERR
INVALID_CHARACTER_ERR
INVALID_MODIFICATION_ERR
INVALID_STATE_ERR
NAMESPACE_ERR
NOT_FOUND_ERR

NOT_SUPPORTED_ERR	
INUSE_ATTRIBUTE_ERR	
NO_DATA_ALLOWED_ERR	
NO_MODIFICATION_ALLOWED_ERR	
SYNTAX_ERR	
WRONG_DOCUMENT_ERR	

Conformance

This section describes the conformance requirements and relationships between the Python DOM API, the W3C DOM recommendations, and the OMG IDL mapping for Python.

Type Mapping

The IDL types used in the DOM specification are mapped to Python types according to the following table.

IDL Type	Python Type
`boolean`	`int`
`int`	`int`
`long int`	`long int`
`unsigned int`	`long int`
`DOMString`	`bytes`
`Node`	`None`

Accessor Methods

The mapping from OMG IDL to Python defines accessor functions for IDL `attribute` declarations in much the way the Java mapping does. Mapping the IDL declarations

```
readonly attribute string someValue;
         attribute string anotherValue;
```

yields three accessor functions: a “get” method for **`someValue`** (**`_get_someValue()`**), and “get” and “set” methods for **`anotherValue`** (**`_get_anotherValue()`** and **`_set_anotherValue()`**). The mapping, in particular, does not require that the IDL attributes are accessible as normal Python attributes: `object.someValue` is *not* required to work, and may

raise an **`AttributeError`**.

The Python DOM API, however, *does* require that normal attribute access work. This means that the typical surrogates generated by Python IDL compilers are not likely to work, and wrapper objects may be needed on the client if the DOM objects are accessed via CORBA. While this does require some additional consideration for CORBA DOM clients, the implementers with experience using DOM over CORBA from Python do not consider this a problem. Attributes that are declared `readonly` may not restrict write access in all DOM implementations.

In the Python DOM API, accessor functions are not required. If provided, they should take the form defined by the Python IDL mapping, but these methods are considered unnecessary since the attributes are accessible directly from Python. “Set” accessors should never be provided for `readonly` attributes.

The IDL definitions do not fully embody the requirements of the W3C DOM API, such as the notion of certain objects, such as the return value of **`getElementsByTagName()`**, being “live”. The Python DOM API does not require implementations to enforce such requirements.

`xml.dom.minidom` — Minimal DOM implementation

Source code: Lib/xml/dom/minidom.py [https://github.com/python/cpython/tree/3.11/Lib/xml/dom/minidom.py]

`xml.dom.minidom` is a minimal implementation of the Document Object Model interface, with an API similar to that in other languages. It is intended to be simpler than the full DOM and also significantly smaller. Users who are not already proficient with the DOM should consider using the `xml.etree.ElementTree` module for their XML processing instead.

Warning

The `xml.dom.minidom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

DOM applications typically start by parsing some XML into a DOM. With `xml.dom.minidom`, this is done through the parse functions:

```
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\\temp\\mydata.xml')  # parse an XML fil

datasource = open('c:\\temp\\mydata.xml')
dom2 = parse(datasource)  # parse an open file

dom3 = parseString('<myxml>Some data<empty/> some more c
```

The `parse()` function can take either a filename or an open file object.

xml.dom.minidom.parse(*filename_or_file*, *parser*=*None*, *bufsize*=*None*)

> Return a **Document** from the given input. *filename_or_file* may be either a file name, or a file-like object. *parser*, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the **parseString()** function instead:

xml.dom.minidom.parseString(*string*, *parser*=*None*)

> Return a **Document** that represents the *string*. This method creates an **io.StringIO** object for the string and passes that on to **parse()**.

Both functions return a **Document** object representing the content of the document.

What the **parse()** and **parseString()** functions do is connect an XML parser with a "DOM builder" that can accept parse events from any SAX parser and convert them into a DOM tree. The name of the functions are perhaps misleading, but are easy to grasp when learning the interfaces. The parsing of the document will be completed before these functions return; it's simply that these functions do not provide a parser implementation themselves.

You can also create a **Document** by calling a method on a "DOM Implementation" object. You can get this object either by calling the **getDOMImplementation()** function in the **xml.dom** package or the **xml.dom.minidom** module. Once you have a **Document**, you can add child nodes to it to populate the DOM:

```
from xml.dom.minidom import getDOMImplementation

impl = getDOMImplementation()

newdoc = impl.createDocument(None, "some_tag", None)
```

```
top_element = newdoc.documentElement
text = newdoc.createTextNode('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification. The main property of the document object is the **`documentElement`** property. It gives you the main element in the XML document: the one that holds all others. Here is an example program:

```
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM tree, you may optionally call the **`unlink()`** method to encourage early cleanup of the now-unneeded objects. **`unlink()`** is an **`xml.dom.minidom`**-specific extension to the DOM API that renders the node and its descendants essentially useless. Otherwise, Python's garbage collector will eventually take care of the objects in the tree.

See also

Document Object Model (DOM) Level 1 Specification **[https://www.w3.org/TR/REC-DOM-Level-1/]**
The W3C recommendation for the DOM supported by **`xml.dom.minidom`**.

DOM Objects

The definition of the DOM API for Python is given as part of the **`xml.dom`** module documentation. This section lists the differences between the API and **`xml.dom.minidom`**.

Node.unlink()
Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM

objects as soon as they are no longer needed is good practice. This only needs to be called on the **Document** object, but may be called on child nodes to discard children of that node.

You can avoid calling this method explicitly by using the **with** statement. The following code will automatically unlink *dom* when the **with** block is exited:

```
with xml.dom.minidom.parse(datasource) as dom:
    ... # Work with dom.
```

Node.writexml(*writer*, *indent*=*''*, *addindent*=*''*, *newl*=*''*, *encoding*=*None*, *standalone*=*None*)

Write XML to the writer object. The writer receives texts but not bytes as input, it should have a **write()** method which matches that of the file object interface. The *indent* parameter is the indentation of the current node. The *addindent* parameter is the incremental indentation to use for subnodes of the current one. The *newl* parameter specifies the string to use to terminate newlines.

For the **Document** node, an additional keyword argument *encoding* can be used to specify the encoding field of the XML header.

Similarly, explicitly stating the *standalone* argument causes the standalone document declarations to be added to the prologue of the XML document. If the value is set to `True`, `standalone="yes"` is added, otherwise it is set to `"no"`. Not stating the argument will omit the declaration from the document.

Changed in version 3.8: The **writexml()** method now preserves the attribute order specified by the user.

Changed in version 3.9: The *standalone* parameter was added.

Node.toxml(*encoding*=*None*, *standalone*=*None*)

Return a string or byte string containing the XML represented by the DOM node.

With an explicit *encoding* 1 argument, the result is a byte string in the specified encoding. With no *encoding* argument, the result is a Unicode string, and the XML declaration in the resulting string does not specify an encoding. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

The *standalone* argument behaves exactly as in **`writexml()`**.

Changed in version 3.8: The **`toxml()`** method now preserves the attribute order specified by the user.

Changed in version 3.9: The *standalone* parameter was added.

Node.toprettyxml(*indent*='\t', *newl*='\n', *encoding*=*None*, *standalone*=*None*)

Return a pretty-printed version of the document. *indent* specifies the indentation string and defaults to a tabulator; *newl* specifies the string emitted at the end of each line and defaults to `\n`.

The *encoding* argument behaves like the corresponding argument of **`toxml()`**.

The *standalone* argument behaves exactly as in **`writexml()`**.

Changed in version 3.8: The **`toprettyxml()`** method now preserves the attribute order specified by the user.

Changed in version 3.9: The *standalone* parameter was added.

DOM Example

This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```
import xml.dom.minidom

document = """\
```

```
<slideshow>
<title>Demo slideshow</title>
<slide><title>Slide title</title>
<point>This is a demo</point>
<point>Of a program for processing slides</point>
</slide>

<slide><title>Another demo slide</title>
<point>It is important</point>
<point>To have more than</point>
<point>one slide</point>
</slide>
</slideshow>
"""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = []
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc.append(node.data)
    return ''.join(rc)

def handleSlideshow(slideshow):
    print("<html>")
    handleSlideshowTitle(slideshow.getElementsByTagName(
    slides = slideshow.getElementsByTagName("slide")
    handleToc(slides)
    handleSlides(slides)
    print("</html>")

def handleSlides(slides):
    for slide in slides:
        handleSlide(slide)

def handleSlide(slide):
    handleSlideTitle(slide.getElementsByTagName("title")
```

```
    handlePoints(slide.getElementsByTagName("point"))

def handleSlideshowTitle(title):
    print(f"<title>{getText(title.childNodes)}</title>")

def handleSlideTitle(title):
    print(f"<h2>{getText(title.childNodes)}</h2>")

def handlePoints(points):
    print("<ul>")
    for point in points:
        handlePoint(point)
    print("</ul>")

def handlePoint(point):
    print(f"<li>{getText(point.childNodes)}</li>")

def handleToc(slides):
    for slide in slides:
        title = slide.getElementsByTagName("title")[0]
        print(f"<p>{getText(title.childNodes)}</p>")

handleSlideshow(dom)
```

minidom and the DOM standard

The **`xml.dom.minidom`** module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply:

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the **`Document`** object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only **`in`**

parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. `void` operations return `None`.

- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods **`_get_foo()`** and **`_set_foo()`**. `readonly` attributes must not be changed; this is not enforced at runtime.
- The types `short int`, `unsigned int`, `unsigned long long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. **`xml.dom.minidom`** supports either bytes or strings, but will normally produce strings. Values of type `DOMString` may also be `None` where allowed to have the IDL `null` value by the DOM specification from the W3C.
- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`); they must not be changed.
- `DOMException` is currently not supported in **`xml.dom.minidom`**. Instead, **`xml.dom.minidom`** uses standard Python exceptions such as **`TypeError`** and **`AttributeError`**.
- **`NodeList`** objects are implemented using Python's built-in list type. These objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more "Pythonic" than the interface defined in the W3C recommendations.

The following interfaces have no implementation in **`xml.dom.minidom`**:

- **`DOMTimeStamp`**
- **`EntityReference`**

Most of these reflect information in the XML document that is not of general utility to most DOM users.

Footnotes

1

The encoding name included in the XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not valid in an XML document’s declaration, even though Python accepts it as an encoding name. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

`xml.dom.pulldom` — Support for building partial DOM trees

Source code: Lib/xml/dom/pulldom.py [https://github.com/python/cpython/tree/3.11/Lib/xml/dom/pulldom.py]

The `xml.dom.pulldom` module provides a "pull parser" which can also be asked to produce DOM-accessible fragments of the document where necessary. The basic concept involves pulling "events" from a stream of incoming XML and processing them. In contrast to SAX which also employs an event-driven processing model together with callbacks, the user of a pull parser is responsible for explicitly pulling events from the stream, looping over those events until either processing is finished or an error condition occurs.

Warning

The `xml.dom.pulldom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

Changed in version 3.7.1: The SAX parser no longer processes general external entities by default to increase security by default. To enable processing of external entities, pass a custom parser instance in:

```
from xml.dom.pulldom import parse
from xml.sax import make_parser
from xml.sax.handler import feature_external_ges

parser = make_parser()
parser.setFeature(feature_external_ges, True)
parse(filename, parser=parser)
```

Example:

```
from xml.dom import pulldom

doc = pulldom.parse('sales_items.xml')
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.tagName =
        if int(node.getAttribute('price')) > 50:
            doc.expandNode(node)
            print(node.toxml())
```

`event` is a constant and can be one of:

- **`START_ELEMENT`**
- **`END_ELEMENT`**
- **`COMMENT`**
- **`START_DOCUMENT`**
- **`END_DOCUMENT`**
- **`CHARACTERS`**
- **`PROCESSING_INSTRUCTION`**
- **`IGNORABLE_WHITESPACE`**

`node` is an object of type **`xml.dom.minidom.Document`**, **`xml.dom.minidom.Element`** or **`xml.dom.minidom.Text`**.

Since the document is treated as a "flat" stream of events, the document "tree" is implicitly traversed and the desired elements are found regardless of their depth in the tree. In other words, one does not need to consider hierarchical issues such as recursive searching of the document nodes, although if the context of elements were important, one would either need to maintain some context-related state (i.e. remembering where one is in the document at any given point) or to make use of the **`DOMEventStream.expandNode()`** method and switch to DOM-related processing.

class xml.dom.pulldom.PullDom(*documentFactory=None*)

Subclass of **`xml.sax.handler.ContentHandler`**.

class xml.dom.pulldom.SAX2DOM(*documentFactory=None*)

Subclass of **`xml.sax.handler.ContentHandler`**.

xml.dom.pulldom.parse(*stream_or_string*, *parser*=*None*, *bufsize*=*None*)

Return a **DOMEventStream** from the given input. *stream_or_string* may be either a file name, or a file-like object. *parser*, if given, must be an **XMLReader** object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the **parseString()** function instead:

xml.dom.pulldom.parseString(*string*, *parser*=*None*)

Return a **DOMEventStream** that represents the (Unicode) *string*.

xml.dom.pulldom.default_bufsize

Default value for the *bufsize* parameter to **parse()**.

The value of this variable can be changed before calling **parse()** and the new value will take effect.

DOMEventStream Objects

class xml.dom.pulldom.DOMEventStream(*stream*, *parser*, *bufsize*)

Changed in version 3.11: Support for **__getitem__()** method has been removed.

getEvent()

Return a tuple containing *event* and the current *node* as **xml.dom.minidom.Document** if event equals **START_DOCUMENT**, **xml.dom.minidom.Element** if event equals **START_ELEMENT** or **END_ELEMENT** or **xml.dom.minidom.Text** if event equals **CHARACTERS**. The current node does not contain information about its children, unless **expandNode()** is called.

expandNode(*node*)

Expands all children of *node* into *node*. Example:

```
from xml.dom import pulldom

xml = '<html><title>Foo</title> <p>Some text <c
doc = pulldom.parseString(xml)
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.
        # Following statement only prints '<p/>
        print(node.toxml())
        doc.expandNode(node)
        # Following statement prints node with
        print(node.toxml())
```

reset()

`xml.sax` — Support for SAX2 parsers

Source code: Lib/xml/sax/_init_.py [https://github.com/python/cpython/tree/3.11/Lib/xml/sax/_init_.py]

The `xml.sax` package provides a number of modules which implement the Simple API for XML (SAX) interface for Python. The package itself provides the SAX exceptions and the convenience functions which will be most used by users of the SAX API.

Warning

The `xml.sax` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

Changed in version 3.7.1: The SAX parser no longer processes general external entities by default to increase security. Before, the parser created network connections to fetch remote files or loaded local files from the file system for DTD and entities. The feature can be enabled again with method `setFeature()` on the parser object and argument `feature_external_ges`.

The convenience functions are:

xml.sax.make_parser(*parser_list=[]*)

Create and return a SAX `XMLReader` object. The first parser found will be used. If *parser_list* is provided, it must be an iterable of strings which name modules that have a function named `create_parser()`. Modules listed in *parser_list* will be used before modules in the default list of parsers.

Changed in version 3.8: The *parser_list* argument can be any

iterable, not just a list.

xml.sax.parse(*filename_or_stream*, *handler*, *error_handler=handler.ErrorHandler()*)

Create a SAX parser and use it to parse a document. The document, passed in as *filename_or_stream*, can be a filename or a file object. The *handler* parameter needs to be a SAX **ContentHandler** instance. If *error_handler* is given, it must be a SAX **ErrorHandler** instance; if omitted, **SAXParseException** will be raised on all errors. There is no return value; all work must be done by the *handler* passed in.

xml.sax.parseString(*string*, *handler*, *error_handler=handler.ErrorHandler()*)

Similar to **parse()**, but parses from a buffer *string* received as a parameter. *string* must be a **str** instance or a bytes-like object.

Changed in version 3.5: Added support of **str** instances.

A typical SAX application uses three kinds of objects: readers, handlers and input sources. “Reader” in this context is another term for parser, i.e. some piece of code that reads the bytes or characters from the input source, and produces a sequence of events. The events then get distributed to the handler objects, i.e. the reader invokes a method on the handler. A SAX application must therefore obtain a reader object, create or open the input sources, create the handlers, and connect these objects all together. As the final step of preparation, the reader is called to parse the input. During parsing, methods on the handler objects are called based on structural and syntactic events from the input data.

For these objects, only the interfaces are relevant; they are normally not instantiated by the application itself. Since Python does not have an explicit notion of interface, they are formally introduced as classes, but applications may use implementations which do not inherit from the provided classes. The **InputSource**, **Locator**, **Attributes**, **AttributesNS**, and **XMLReader** interfaces are

defined in the module **xml.sax.xmlreader**. The handler interfaces are defined in **xml.sax.handler**. For convenience, **InputSource** (which is often instantiated directly) and the handler classes are also available from **xml.sax**. These interfaces are described below.

In addition to these classes, **xml.sax** provides the following exception classes.

exception xml.sax.SAXException(*msg*, *exception*=*None*)

Encapsulate an XML error or warning. This class can contain basic error or warning information from either the XML parser or the application: it can be subclassed to provide additional functionality or to add localization. Note that although the handlers defined in the **ErrorHandler** interface receive instances of this exception, it is not required to actually raise the exception — it is also useful as a container for information.

When instantiated, *msg* should be a human-readable description of the error. The optional *exception* parameter, if given, should be `None` or an exception that was caught by the parsing code and is being passed along as information.

This is the base class for the other SAX exception classes.

exception xml.sax.SAXParseException(*msg*, *exception*, *locator*)

Subclass of **SAXException** raised on parse errors. Instances of this class are passed to the methods of the SAX **ErrorHandler** interface to provide information about the parse error. This class supports the SAX **Locator** interface as well as the **SAXException** interface.

exception xml.sax.SAXNotRecognizedException(*msg*, *exception*=*None*)

Subclass of **SAXException** raised when a SAX **XMLReader** is confronted with an unrecognized feature or property. SAX applications and extensions may use this class for similar purposes.

exception xml.sax.SAXNotSupportedException(*msg*, *exception*=*None*)

Subclass of **SAXException** raised when a SAX **XMLReader** is asked to enable a feature that is not supported, or to set a property to a value that the implementation does not support. SAX applications and extensions may use this class for similar purposes.

Convenience functions for use in SAX applications.

Module **xml.sax.xmlreader**
Definitions of the interfaces for parser-provided objects.

SAXException Objects

The **SAXException** exception class supports the following methods:

SAXException.getMessage()

Return a human-readable message describing the error condition.

SAXException.getException()

Return an encapsulated exception object, or `None`.

`xml.sax.handler` — Base classes for SAX handlers

Source code: Lib/xml/sax/handler.py [https://github.com/python/cpython/tree/3.11/Lib/xml/sax/handler.py]

The SAX API defines five kinds of handlers: content handlers, DTD handlers, error handlers, entity resolvers and lexical handlers. Applications normally only need to implement those interfaces whose events they are interested in; they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module `xml.sax.handler`, so that all methods get default implementations.

class xml.sax.handler.ContentHandler

This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

class xml.sax.handler.DTDHandler

Handle DTD events.

This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

class xml.sax.handler.EntityResolver

Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.

class xml.sax.handler.ErrorHandler

Interface used by the parser to present error and warning messages to the application. The methods of this object control whether errors are immediately converted to exceptions or are handled in some other way.

class xml.sax.handler.LexicalHandler

Interface used by the parser to represent low frequency events which may not be of interest to many applications.

In addition to these classes, **`xml.sax.handler`** provides symbolic constants for the feature and property names.

xml.sax.handler.feature_namespaces

value: `"http://xml.org/sax/features/namespaces"`
true: Perform Namespace processing.
false: Optionally do not perform Namespace processing (implies namespace-prefixes; default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_namespace_prefixes

value: `"http://xml.org/sax/features/namespace-prefixes"`
true: Report the original prefixed names and attributes used for Namespace declarations.
false: Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_string_interning

value: `"http://xml.org/sax/features/string-interning"`
true: All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function.
false: Names are not necessarily interned, although they may be (default).

access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_validation

value: "http://xml.org/sax/features/validation"
true: Report all validation errors (implies external-general-entities and external-parameter-entities).
false: Do not report validation errors.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_ges

value: "http://xml.org/sax/features/external-general-entities"
true: Include all external general (text) entities.
false: Do not include external general entities.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_pes

value: "http://xml.org/sax/features/external-parameter-entities"
true: Include all external parameter entities, including the external DTD subset.
false: Do not include any external parameter entities, even the external DTD subset.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.all_features

List of all features.

xml.sax.handler.property_lexical_handler

value: "http://xml.org/sax/properties/lexical-handler"
data type: xml.sax.handler.LexicalHandler (not supported in Python 2)
description: An optional extension handler for lexical events like comments.
access: read/write

xml.sax.handler.property_declaration_handler

value: `"http://xml.org/sax/properties/declaration-handler"`
data type: xml.sax.sax2lib.DeclHandler (not supported in Python 2)
description: An optional extension handler for DTD-related events other than notations and unparsed entities.
access: read/write

xml.sax.handler.property_dom_node

value: `"http://xml.org/sax/properties/dom-node"`
data type: org.w3c.dom.Node (not supported in Python 2)
description: When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.property_xml_string

value: `"http://xml.org/sax/properties/xml-string"`
data type: Bytes
description: The literal string of characters that was the source for the current event.
access: read-only

xml.sax.handler.all_properties

List of all known property names.

ContentHandler Objects

Users are expected to subclass **`ContentHandler`** to support their application. The following methods are called by the parser on the appropriate events in the input document:

ContentHandler.setDocumentLocator(*locator*)

Called by the parser to give the application a locator for

locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator: if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application's business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

ContentHandler.startDocument()

Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in DTDHandler (except for `setDocumentLocator()`).

ContentHandler.endDocument()

Receive notification of the end of a document.

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

ContentHandler.startPrefixMapping(*prefix*, *uri*)

Begin the scope of a prefix-URI Namespace mapping.

The information from this event is not necessary for normal Namespace processing: the SAX XML reader will automatically replace prefixes for element and attribute names when the `feature_namespaces` feature is enabled (the default).

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the **`startPrefixMapping()`** and **`endPrefixMapping()`** events supply the information to the application to expand prefixes in those contexts itself, if necessary.

Note that **`startPrefixMapping()`** and **`endPrefixMapping()`** events are not guaranteed to be properly nested relative to each-other: all **`startPrefixMapping()`** events will occur before the corresponding **`startElement()`** event, and all **`endPrefixMapping()`** events will occur after the corresponding **`endElement()`** event, but their order is not guaranteed.

ContentHandler.endPrefixMapping(*prefix*)

End the scope of a prefix-URI mapping.

See **`startPrefixMapping()`** for details. This event will always occur after the corresponding **`endElement()`** event, but the order of **`endPrefixMapping()`** events is not otherwise guaranteed.

ContentHandler.startElement(*name*, *attrs*)

Signals the start of an element in non-namespace mode.

The *name* parameter contains the raw XML 1.0 name of the element type as a string and the *attrs* parameter holds an object of the **`Attributes`** interface (see The Attributes Interface) containing the attributes of the element. The object passed as *attrs* may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the

attributes. To keep a copy of the attributes, use the **`copy()`** method of the *attrs* object.

ContentHandler.endElement(*name*)

Signals the end of an element in non-namespace mode.

The *name* parameter contains the name of the element type, just as with the **`startElement()`** event.

ContentHandler.startElementNS(*name*, *qname*, *attrs*)

Signals the start of an element in namespace mode.

The *name* parameter contains the name of the element type as a `(uri, localname)` tuple, the *qname* parameter contains the raw XML 1.0 name used in the source document, and the *attrs* parameter holds an instance of the **`AttributesNS`** interface (see The AttributesNS Interface) containing the attributes of the element. If no namespace is associated with the element, the *uri* component of *name* will be `None`. The object passed as *attrs* may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the **`copy()`** method of the *attrs* object.

Parsers may set the *qname* parameter to `None`, unless the `feature_namespace_prefixes` feature is activated.

ContentHandler.endElementNS(*name*, *qname*)

Signals the end of an element in namespace mode.

The *name* parameter contains the name of the element type, just as with the **`startElementNS()`** method, likewise the *qname* parameter.

ContentHandler.characters(*content*)

Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous

character data in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

content may be a string or bytes instance; the `expat` reader module always produces strings.

Note

The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use *content* instead of slicing content with the old *offset* and *length* parameters.

ContentHandler.ignorableWhitespace(*whitespace*)

Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10): non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

ContentHandler.processingInstruction(*target, data*)

Receive notification of a processing instruction.

The Parser will invoke this method once for each processing

instruction found: note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

ContentHandler.skippedEntity(*name*)

Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the `feature_external_ges` and the `feature_external_pes` properties.

DTDHandler Objects

`DTDHandler` instances provide the following methods:

DTDHandler.notationDecl(*name*, *publicId*, *systemId*)

Handle a notation declaration event.

DTDHandler.unparsedEntityDecl(*name*, *publicId*, *systemId*, *ndata*)

Handle an unparsed entity declaration event.

EntityResolver Objects

EntityResolver.resolveEntity(*publicId*, *systemId*)

Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an InputSource to read from. The default implementation returns *systemId*.

ErrorHandler Objects

Objects with this interface are used to receive error and warning information from the **`XMLReader`**. If you create an object that implements this interface, then register the object with your **`XMLReader`**, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available: warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a **`SAXParseException`** as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

ErrorHandler.error(*exception*)

Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

ErrorHandler.fatalError(*exception*)

Called when the parser encounters an error it cannot recover from; parsing is expected to terminate when this method returns.

ErrorHandler.warning(*exception*)

Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.

LexicalHandler Objects

Optional SAX2 handler for lexical events.

This handler is used to obtain lexical information about an XML document. Lexical information includes information describing the document encoding used and XML comments embedded in the

document, as well as section boundaries for the DTD and for any CDATA sections. The lexical handlers are used in the same manner as content handlers.

Set the LexicalHandler of an XMLReader by using the setProperty method with the property identifier `'http://xml.org/sax/properties/lexical-handler'`.

LexicalHandler.comment(*content*)

Reports a comment anywhere in the document (including the DTD and outside the document element).

LexicalHandler.startDTD(*name*, *public_id*, *system_id*)

Reports the start of the DTD declarations if the document has an associated DTD.

LexicalHandler.endDTD()

Reports the end of DTD declaration.

LexicalHandler.startCDATA()

Reports the start of a CDATA marked section.

The contents of the CDATA marked section will be reported through the characters handler.

LexicalHandler.endCDATA()

Reports the end of a CDATA marked section.

`xml.sax.saxutils` — SAX Utilities

Source code: Lib/xml/sax/saxutils.py [https://github.com/python/cpython/tree/3.11/Lib/xml/sax/saxutils.py]

The module `xml.sax.saxutils` contains a number of classes and functions that are commonly useful when creating SAX applications, either in direct use, or as base classes.

xml.sax.saxutils.escape(*data*, *entities={}*)

Escape `'&'`, `'<'`, and `'>'` in a string of data.

You can escape other strings of data by passing a dictionary as the optional *entities* parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. The characters `'&'`, `'<'` and `'>'` are always escaped, even if *entities* is provided.

xml.sax.saxutils.unescape(*data*, *entities={}*)

Unescape `'&'`, `'<'`, and `'>'` in a string of data.

You can unescape other strings of data by passing a dictionary as the optional *entities* parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. `'&amp'`, `'<'`, and `'>'` are always unescaped, even if *entities* is provided.

xml.sax.saxutils.quoteattr(*data*, *entities={}*)

Similar to `escape()`, but also prepares *data* to be used as an attribute value. The return value is a quoted version of *data* with any additional required replacements. `quoteattr()` will select a quote character based on the content of *data*,

attempting to avoid encoding any quote characters in the string. If both single- and double-quote characters are already in *data*, the double-quote characters will be encoded and *data* will be wrapped in double-quotes. The resulting string can be used directly as an attribute value:

```
>>> print("<element attr=%s>" % quoteattr("ab ' cd
<element attr="ab ' cd " ef">
```

This function is useful when generating attribute values for HTML or any SGML using the reference concrete syntax.

class xml.sax.saxutils.XMLGenerator(*out=None*, *encoding='iso-8859-1'*, *short_empty_elements=False*)

This class implements the **ContentHandler** interface by writing SAX events back into an XML document. In other words, using an **XMLGenerator** as the content handler will reproduce the original document being parsed. *out* should be a file-like object which will default to *sys.stdout*. *encoding* is the encoding of the output stream which defaults to `'iso-8859-1'`. *short_empty_elements* controls the formatting of elements that contain no content: if `False` (the default) they are emitted as a pair of start/end tags, if set to `True` they are emitted as a single self-closed tag.

New in version 3.2: The *short_empty_elements* parameter.

class xml.sax.saxutils.XMLFilterBase(*base*)

This class is designed to sit between an **XMLReader** and the client application's event handlers. By default, it does nothing but pass requests up to the reader and events on to the handlers unmodified, but subclasses can override specific methods to modify the event stream or the configuration requests as they pass through.

xml.sax.saxutils.prepare_input_source(*source*, *base=''*)

This function takes an input source and an optional base URL and returns a fully resolved **InputSource** object ready for

reading. The input source can be given as a string, a file-like object, or an **`InputSource`** object; parsers will use this function to implement the polymorphic *source* argument to their **`parse()`** method.

`xml.sax.xmlreader` — Interface for XML parsers

Source code: Lib/xml/sax/xmlreader.py [https://github.com/python/cpython/tree/3.11/Lib/xml/sax/xmlreader.py]

SAX parsers implement the `XMLReader` interface. They are implemented in a Python module, which must provide a function `create_parser()`. This function is invoked by `xml.sax.make_parser()` with no arguments to create a new parser object.

class xml.sax.xmlreader.XMLReader

Base class which can be inherited by SAX parsers.

class xml.sax.xmlreader.IncrementalParser

In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still `parse()` won't return until the entire document is processed. So these interfaces should be used if the blocking behaviour of `parse()` is not desirable.

When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

Note that these methods must *not* be called during parsing, that is, after parse has been called and before it returns.

By default, the class also implements the parse method of the

XMLReader interface using the feed, close and reset methods of the IncrementalParser interface as a convenience to SAX 2.0 driver writers.

class xml.sax.xmlreader.Locator

Interface for associating a SAX event with a document location. A locator object will return valid results only during calls to DocumentHandler methods; at any other time, the results are unpredictable. If information is not available, methods may return `None`.

class xml.sax.xmlreader.InputSource(*system_id=None*)

Encapsulation of the information needed by the **`XMLReader`** to read entities.

This class may include information about the public identifier, system identifier, byte stream (possibly with character encoding information) and/or the character stream of an entity.

Applications will create objects of this class for use in the **`XMLReader.parse()`** method and for returning from EntityResolver.resolveEntity.

An **`InputSource`** belongs to the application, the **`XMLReader`** is not allowed to modify **`InputSource`** objects passed to it from the application, although it may make copies and modify those.

class xml.sax.xmlreader.AttributesImpl(*attrs*)

This is an implementation of the **`Attributes`** interface (see section The Attributes Interface). This is a dictionary-like object which represents the element attributes in a **`startElement()`** call. In addition to the most useful dictionary operations, it supports a number of other methods as described by the interface. Objects of this class should be instantiated by readers; *attrs* must be a dictionary-like object containing a mapping from attribute names to attribute values.

class xml.sax.xmlreader.AttributesNSImpl(*attrs*, *qnames*)

Namespace-aware variant of **AttributesImpl**, which will be passed to **startElementNS()**. It is derived from **AttributesImpl**, but understands attribute names as two-tuples of *namespaceURI* and *localname*. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the **AttributesNS** interface (see section The AttributesNS Interface).

XMLReader Objects

The **XMLReader** interface supports the following methods:

XMLReader.parse(*source*)

Process an input source, producing SAX events. The *source* object can be a system identifier (a string identifying the input source – typically a file name or a URL), a **pathlib.Path** or path-like object, or an **InputSource** object. When **parse()** returns, the input is completely processed, and the parser object can be discarded or reset.

Changed in version 3.5: Added support of character streams.

Changed in version 3.8: Added support of path-like objects.

XMLReader.getContentHandler()

Return the current **ContentHandler**.

XMLReader.setContentHandler(*handler*)

Set the current **ContentHandler**. If no **ContentHandler** is set, content events will be discarded.

XMLReader.getDTDHandler()

Return the current **DTDHandler**.

XMLReader.setDTDHandler(*handler*)

Set the current **DTDHandler**. If no **DTDHandler** is set, DTD events will be discarded.

XMLReader.getEntityResolver()

Return the current **EntityResolver**.

XMLReader.setEntityResolver(*handler*)

Set the current **EntityResolver**. If no **EntityResolver** is set, attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

XMLReader.getErrorHandler()

Return the current **ErrorHandler**.

XMLReader.setErrorHandler(*handler*)

Set the current error handler. If no **ErrorHandler** is set, errors will be raised as exceptions, and warnings will be printed.

XMLReader.setLocale(*locale*)

Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must raise a SAX exception. Applications may request a locale change in the middle of a parse.

XMLReader.getFeature(*featurename*)

Return the current setting for feature *featurename*. If the feature is not recognized, **SAXNotRecognizedException** is raised. The well-known featurenames are listed in the module **xml.sax.handler**.

XMLReader.setFeature(*featurename*, *value*)

Set the *featurename* to *value*. If the feature is not recognized,

SAXNotRecognizedException is raised. If the feature or its setting is not supported by the parser, *SAXNotSupportedException* is raised.

XMLReader.getProperty(*propertyname*)

Return the current setting for property *propertyname*. If the property is not recognized, a **SAXNotRecognizedException** is raised. The well-known propertynames are listed in the module **xml.sax.handler**.

XMLReader.setProperty(*propertyname*, *value*)

Set the *propertyname* to *value*. If the property is not recognized, **SAXNotRecognizedException** is raised. If the property or its setting is not supported by the parser, *SAXNotSupportedException* is raised.

IncrementalParser Objects

Instances of **IncrementalParser** offer the following additional methods:

IncrementalParser.feed(*data*)

Process a chunk of *data*.

IncrementalParser.close()

Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

IncrementalParser.reset()

This method is called after close has been called to reset the parser so that it is ready to parse new documents. The results of calling parse or feed after close without calling reset are undefined.

Locator Objects

Instances of `Locator` provide these methods:

Locator.getColumnNumber()
: Return the column number where the current event begins.

Locator.getLineNumber()
: Return the line number where the current event begins.

Locator.getPublicId()
: Return the public identifier for the current event.

Locator.getSystemId()
: Return the system identifier for the current event.

InputSource Objects

InputSource.setPublicId(*id*)
: Sets the public identifier of this `InputSource`.

InputSource.getPublicId()
: Returns the public identifier of this `InputSource`.

InputSource.setSystemId(*id*)
: Sets the system identifier of this `InputSource`.

InputSource.getSystemId()
: Returns the system identifier of this `InputSource`.

InputSource.setEncoding(*encoding*)
: Sets the character encoding of this `InputSource`.

  The encoding must be a string acceptable for an XML

encoding declaration (see section 4.3.3 of the XML recommendation).

The encoding attribute of the **`InputSource`** is ignored if the **`InputSource`** also contains a character stream.

InputSource.getEncoding()

Get the character encoding of this InputSource.

InputSource.setByteStream(*bytefile*)

Set the byte stream (a binary file) for this input source.

The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.

If the application knows the character encoding of the byte stream, it should set it with the setEncoding method.

InputSource.getByteStream()

Get the byte stream for this input source.

The getEncoding method will return the character encoding for this byte stream, or `None` if unknown.

InputSource.setCharacterStream(*charfile*)

Set the character stream (a text file) for this input source.

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

InputSource.getCharacterStream()

Get the character stream for this input source.

The `Attributes` Interface

Attributes objects implement a portion of the mapping protocol, including the methods **copy()**, **get()**, **__contains__()**, **items()**, **keys()**, and **values()**. The following methods are also provided:

Attributes.getLength()

Return the number of attributes.

Attributes.getNames()

Return the names of the attributes.

Attributes.getType(*name*)

Returns the type of the attribute *name*, which is normally `'CDATA'`.

Attributes.getValue(*name*)

Return the value of attribute *name*.

The **AttributesNS** Interface

This interface is a subtype of the **Attributes** interface (see section The Attributes Interface). All methods supported by that interface are also available on **AttributesNS** objects.

The following methods are also available:

AttributesNS.getValueByQName(*name*)

Return the value for a qualified name.

AttributesNS.getNameByQName(*name*)

Return the `(namespace, localname)` pair for a qualified *name*.

AttributesNS.getQNameByName(*name*)

Return the qualified name for a `(namespace, localname)` pair.

AttributesNS.getQNames()

Return the qualified names of all attributes.

`xml.parsers.expat` — Fast XML parsing using Expat

Warning

The **`pyexpat`** module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

The **`xml.parsers.expat`** module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, **`xmlparser`**, that represents the current state of an XML parser. After an **`xmlparser`** object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the **`pyexpat`** module to provide access to the Expat parser. Direct use of the **`pyexpat`** module is deprecated.

This module provides one exception and one type object:

exception xml.parsers.expat.ExpatError

The exception raised when Expat reports an error. See section ExpatError Exceptions for more information on interpreting Expat errors.

exception xml.parsers.expat.error

Alias for **`ExpatError`**.

xml.parsers.expat.XMLParserType

The type of the return values from the **`ParserCreate()`** function.

The **xml.parsers.expat** module contains two functions:

xml.parsers.expat.ErrorString(*errno*)

Returns an explanatory string for a given error number *errno*.

xml.parsers.expat.ParserCreate(*encoding*=*None*, *namespace_separator*=*None*)

Creates and returns a new **xmlparser** object. *encoding*, if specified, must be a string naming the encoding used by the XML data. Expat doesn't support as many encodings as Python does, and its repertoire of encodings can't be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If *encoding* 1 is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for *namespace_separator*. The value must be a one-character string; a **ValueError** will be raised if the string has an illegal length (`None` is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlers **StartElementHandler** and **EndElementHandler** will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (`chr(0)`) then the namespace URI and the local part will be concatenated without any separator.

For example, if *namespace_separator* is set to a space character (`' '`) and the following document is parsed:

```
<?xml version="1.0"?>
<root xmlns    = "http://default-namespace.org/"
      xmlns:py = "http://www.python.org/ns/">
  <py:elem1 />
  <elem2 xmlns="" />
</root>
```

StartElementHandler will receive the following strings for each element:

```
http://default-namespace.org/ root
http://www.python.org/ns/ elem1
elem2
```

Due to limitations in the `Expat` library used by **pyexpat**, the **xmlparser** instance returned can only be used to parse a single XML document. Call `ParserCreate` for each document to provide unique parser instances.

See also

The Expat XML Parser **[http://www.libexpat.org/]**
Home page of the Expat project.

XMLParser Objects

xmlparser objects have the following methods:

xmlparser.Parse(*data*[, *isfinal*])

Parses the contents of the string *data*, calling the appropriate handler functions to process the parsed data. *isfinal* must be true on the final call to this method; it allows the parsing of a single file in fragments, not the submission of multiple files. *data* can be the empty string at any time.

xmlparser.ParseFile(*file*)

Parse XML data reading from the object *file*. *file* only needs to provide the `read(nbytes)` method, returning the empty string when there's no more data.

xmlparser.SetBase(*base*)

Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application: this value will be passed through as the

base argument to the **ExternalEntityRefHandler()**, **NotationDeclHandler()**, and **UnparsedEntityDeclHandler()** functions.

xmlparser.GetBase()

Returns a string containing the base set by a previous call to **SetBase()**, or `None` if **SetBase()** hasn't been called.

xmlparser.GetInputContext()

Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text. When called while an event handler is not active, the return value is `None`.

xmlparser.ExternalEntityParserCreate(*context*[, *encoding*])

Create a "child" parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The *context* parameter should be the string passed to the **ExternalEntityRefHandler()** handler function, described below. The child parser is created with the **ordered_attributes** and **specified_attributes** set to the values of this parser.

xmlparser.SetParamEntityParsing(*flag*)

Control parsing of parameter entities (including the external DTD subset). Possible *flag* values are **XML_PARAM_ENTITY_PARSING_NEVER**, **XML_PARAM_ENTITY_PARSING_UNLESS_STANDALONE** and **XML_PARAM_ENTITY_PARSING_ALWAYS**. Return true if setting the flag was successful.

xmlparser.UseForeignDTD([*flag*])

Calling this with a true value for *flag* (the default) will cause Expat to call the **ExternalEntityRefHandler** with **None** for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the **ExternalEntityRefHandler** will still be called, but

the **StartDoctypeDeclHandler** and **EndDoctypeDeclHandler** will not be called.

Passing a false value for *flag* will cancel a previous call that passed a true value, but otherwise has no effect.

This method can only be called before the **Parse()** or **ParseFile()** methods are called; calling it after either of those have been called causes **ExpatError** to be raised with the **code** attribute set to `errors.codes[errors.XML_ERROR_CANT_CHANGE_FEATURE_O`

xmlparser objects have the following attributes:

xmlparser.buffer_size

The size of the buffer used when **buffer_text** is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

xmlparser.buffer_text

Setting this to true causes the **xmlparser** object to buffer textual content returned by Expat to avoid multiple calls to the **CharacterDataHandler()** callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time.

xmlparser.buffer_used

If **buffer_text** is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when **buffer_text** is false.

xmlparser.ordered_attributes

Setting this attribute to a non-zero integer causes the attributes to be reported as a list rather than a dictionary. The attributes are presented in the order found in the document

text. For each attribute, two list entries are presented: the attribute name and the attribute value. (Older versions of this module also used this format.) By default, this attribute is false; it may be changed at any time.

xmlparser.specified_attributes

If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false; it may be changed at any time.

The following attributes contain values relating to the most recent error encountered by an **xmlparser** object, and will only have correct values once a call to **Parse()** or **ParseFile()** has raised an **xml.parsers.expat.ExpatError** exception.

xmlparser.ErrorByteIndex

Byte index at which an error occurred.

xmlparser.ErrorCode

Numeric code specifying the problem. This value can be passed to the **ErrorString()** function, or compared to one of the constants defined in the `errors` object.

xmlparser.ErrorColumnNumber

Column number at which an error occurred.

xmlparser.ErrorLineNumber

Line number at which an error occurred.

The following attributes contain values relating to the current parse location in an **xmlparser** object. During a callback reporting a parse event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a

callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

xmlparser.CurrentByteIndex

Current byte index in the parser input.

xmlparser.CurrentColumnNumber

Current column number in the parser input.

xmlparser.CurrentLineNumber

Current line number in the parser input.

Here is the list of handlers that can be set. To set a handler on an **xmlparser** object *o*, use `o.handlername = func`. *handlername* must be taken from the following list, and *func* must be a callable object accepting the correct number of arguments. The arguments are all strings, unless otherwise stated.

xmlparser.XmlDeclHandler(*version*, *encoding*, *standalone*)

Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional "standalone" declaration. *version* and *encoding* will be strings, and *standalone* will be `1` if the document is declared standalone, `0` if it is declared not to be standalone, or `-1` if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

xmlparser.StartDoctypeDeclHandler(*doctypeName*, *systemId*, *publicId*, *has_internal_subset*)

Called when Expat begins parsing the document type declaration (`<!DOCTYPE ...`). The *doctypeName* is provided exactly as presented. The *systemId* and *publicId* parameters give the system and public identifiers if specified, or `None` if omitted. *has_internal_subset* will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

xmlparser.EndDoctypeDeclHandler()

Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

xmlparser.ElementDeclHandler(*name*, *model*)

Called once for each element type declaration. *name* is the name of the element type, and *model* is a representation of the content model.

xmlparser.AttlistDeclHandler(*elname*, *attname*, *type*, *default*, *required*)

Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. *elname* is the name of the element to which the declaration applies and *attname* is the name of the attribute declared. The attribute type is a string passed as *type*; the possible values are `'CDATA'`, `'ID'`, `'IDREF'`, ... *default* gives the default value for the attribute used when the attribute is not specified by the document instance, or `None` if there is no default value (`#IMPLIED` values). If the attribute is required to be given in the document instance, *required* will be true. This requires Expat version 1.95.0 or newer.

xmlparser.StartElementHandler(*name*, *attributes*)

Called for the start of every element. *name* is a string containing the element name, and *attributes* is the element attributes. If **`ordered_attributes`** is true, this is a list (see **`ordered_attributes`** for a full description). Otherwise it's a dictionary mapping names to values.

xmlparser.EndElementHandler(*name*)

Called for the end of every element.

xmlparser.ProcessingInstructionHandler(*target*, *data*)

Called for every processing instruction.

xmlparser.CharacterDataHandler(*data*)

Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the **`StartCdataSectionHandler`**, **`EndCdataSectionHandler`**, and **`ElementDeclHandler`** callbacks to collect the required information.

xmlparser.UnparsedEntityDeclHandler(*entityName*, *base*, *systemId*, *publicId*, *notationName*)

Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use **`EntityDeclHandler`** instead. (The underlying function in the Expat library has been declared obsolete.)

xmlparser.EntityDeclHandler(*entityName*, *is_parameter_entity*, *value*, *base*, *systemId*, *publicId*, *notationName*)

Called for all entity declarations. For parameter and internal entities, *value* will be a string giving the declared contents of the entity; this will be `None` for external entities. The *notationName* parameter will be `None` for parsed entities, and the name of the notation for unparsed entities. *is_parameter_entity* will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

xmlparser.NotationDeclHandler(*notationName*, *base*, *systemId*, *publicId*)

Called for notation declarations. *notationName*, *base*, and *systemId*, and *publicId* are strings if given. If the public identifier is omitted, *publicId* will be `None`.

xmlparser.StartNamespaceDeclHandler(*prefix*, *uri*)

Called when an element contains a namespace declaration. Namespace declarations are processed before the **`StartElementHandler`** is called for the element on which

declarations are placed.

xmlparser.EndNamespaceDeclHandler(*prefix*)

Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each namespace declaration on the element in the reverse of the order for which the **`StartNamespaceDeclHandler`** was called to indicate the start of each namespace declaration's scope. Calls to this handler are made after the corresponding **`EndElementHandler`** for the end of the element.

xmlparser.CommentHandler(*data*)

Called for comments. *data* is the text of the comment, excluding the leading `'<!--'` and trailing `'-->'`.

xmlparser.StartCdataSectionHandler()

Called at the start of a CDATA section. This and **`EndCdataSectionHandler`** are needed to be able to identify the syntactical start and end for CDATA sections.

xmlparser.EndCdataSectionHandler()

Called at the end of a CDATA section.

xmlparser.DefaultHandler(*data*)

Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

xmlparser.DefaultHandlerExpand(*data*)

This is the same as the **`DefaultHandler()`**, but doesn't inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

xmlparser.NotStandaloneHandler()

Called if the XML document hasn't been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to `yes` in an XML declaration. If this handler returns `0`, then the parser will raise an **`XML_ERROR_NOT_STANDALONE`** error. If this handler is not set, no exception is raised by the parser for this condition.

xmlparser.ExternalEntityRefHandler(*context*, *base*, *systemId*, *publicId*)

Called for references to external entities. *base* is the current base, as set by a previous call to **`SetBase()`**. The public and system identifiers, *systemId* and *publicId*, are strings if given; if the public identifier is not given, *publicId* will be `None`. The *context* value is opaque and should only be used as described below.

For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using `ExternalEntityParserCreate(context)`, initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns `0`, the parser will raise an **`XML_ERROR_EXTERNAL_ENTITY_HANDLING`** error, otherwise parsing will continue.

If this handler is not provided, external entities are reported by the **`DefaultHandler`** callback, if provided.

ExpatError Exceptions

`ExpatError` exceptions have a number of interesting attributes:

ExpatError.code

Expat's internal error number for the specific error. The **`errors.messages`** dictionary maps these error numbers to Expat's error messages. For example:

```
from xml.parsers.expat import ParserCreate, ExpatEr

p = ParserCreate()
try:
    p.Parse(some_xml_document)
except ExpatError as err:
    print("Error:", errors.messages[err.code])
```

The **errors** module also provides error message constants and a dictionary **codes** mapping these messages back to the error codes, see below.

ExpatError.lineno

Line number on which the error was detected. The first line is numbered `1`.

ExpatError.offset

Character offset into the line where the error occurred. The first column is numbered `0`.

Example

The following program defines three handlers that just print out their arguments.

```
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print('Start element:', name, attrs)
def end_element(name):
    print('End element:', name)
def char_data(data):
    print('Character data:', repr(data))

p = xml.parsers.expat.ParserCreate()

p.StartElementHandler = start_element
```

```
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version="1.0"?>
<parent id="top"><child1 name="paul">Text goes here</chi
<child2 name="fred">More text</child2>
</parent>""", 1)
```

The output from this program is:

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
Character data: '\n'
Start element: child2 {'name': 'fred'}
Character data: 'More text'
End element: child2
Character data: '\n'
End element: parent
```

Content Model Descriptions

Content models are described using nested tuples. Each tuple contains four values: the type, the quantifier, the name, and a tuple of children. Children are simply additional content model descriptions.

The values of the first two fields are constants defined in the **`xml.parsers.expat.model`** module. These constants can be collected in two groups: the model type group and the quantifier group.

The constants in the model type group are:

xml.parsers.expat.model.XML_CTYPE_ANY

> The element named by the model name was declared to have a content model of `ANY`.

xml.parsers.expat.model.XML_CTYPE_CHOICE

The named element allows a choice from a number of options; this is used for content models such as `(A | B | C)`.

xml.parsers.expat.model.XML_CTYPE_EMPTY

Elements which are declared to be `EMPTY` have this model type.

xml.parsers.expat.model.XML_CTYPE_MIXED

xml.parsers.expat.model.XML_CTYPE_NAME

xml.parsers.expat.model.XML_CTYPE_SEQ

Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as `(A, B, C)`.

The constants in the quantifier group are:

xml.parsers.expat.model.XML_CQUANT_NONE

No modifier is given, so it can appear exactly once, as for `A`.

xml.parsers.expat.model.XML_CQUANT_OPT

The model is optional: it can appear once or not at all, as for `A?`.

xml.parsers.expat.model.XML_CQUANT_PLUS

The model must occur one or more times (like `A+`).

xml.parsers.expat.model.XML_CQUANT_REP

The model must occur zero or more times, as for `A*`.

Expat error constants

The following constants are provided in the **`xml.parsers.expat.errors`** module. These constants are useful

in interpreting some of the attributes of the **ExpatError** exception objects raised when an error has occurred. Since for backwards compatibility reasons, the constants' value is the error *message* and not the numeric error *code*, you do this by comparing its **code** attribute with `errors.codes[errors.XML_ERROR_`*CONSTANT_NAME*`]`.

The `errors` module has the following attributes:

xml.parsers.expat.errors.codes

A dictionary mapping string descriptions to their error codes.

New in version 3.2.

xml.parsers.expat.errors.messages

A dictionary mapping numeric error codes to their string descriptions.

New in version 3.2.

xml.parsers.expat.errors.XML_ERROR_ASYNC_ENTITY

xml.parsers.expat.errors.XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF

An entity reference in an attribute value referred to an external entity instead of an internal entity.

xml.parsers.expat.errors.XML_ERROR_BAD_CHAR_REF

A character reference referred to a character which is illegal in XML (for example, character `0`, or '&#0;').

xml.parsers.expat.errors.XML_ERROR_BINARY_ENTITY_REF

An entity reference referred to an entity which was declared with a notation, so cannot be parsed.

xml.parsers.expat.errors.XML_ERROR_DUPLICATE_ATTRIBUTE

An attribute was used more than once in a start tag.

xml.parsers.expat.errors.XML_ERROR_INCORRECT_ENCODING

xml.parsers.expat.errors.XML_ERROR_INVALID_TOKEN

Raised when an input byte could not properly be assigned to a character; for example, a NUL byte (value `0`) in a UTF-8 input stream.

xml.parsers.expat.errors.XML_ERROR_JUNK_AFTER_DOC_ELEMENT

Something other than whitespace occurred after the document element.

xml.parsers.expat.errors.XML_ERROR_MISPLACED_XML_PI

An XML declaration was found somewhere other than the start of the input data.

xml.parsers.expat.errors.XML_ERROR_NO_ELEMENTS

The document contains no elements (XML requires all documents to contain exactly one top-level element)..

xml.parsers.expat.errors.XML_ERROR_NO_MEMORY

Expat was not able to allocate memory internally.

xml.parsers.expat.errors.XML_ERROR_PARAM_ENTITY_REF

A parameter entity reference was found where it was not allowed.

xml.parsers.expat.errors.XML_ERROR_PARTIAL_CHAR

An incomplete character was found in the input.

xml.parsers.expat.errors.XML_ERROR_RECURSIVE_ENTITY_REF

An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

xml.parsers.expat.errors.XML_ERROR_SYNTAX

Some unspecified syntax error was encountered.

xml.parsers.expat.errors.XML_ERROR_TAG_MISMATCH

An end tag did not match the innermost open start tag.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_TOKEN

Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

xml.parsers.expat.errors.XML_ERROR_UNDEFINED_ENTITY

A reference was made to an entity which was not defined.

xml.parsers.expat.errors.XML_ERROR_UNKNOWN_ENCODING

The document encoding is not supported by Expat.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_CDATA_SECTION

A CDATA marked section was not closed.

xml.parsers.expat.errors.XML_ERROR_EXTERNAL_ENTITY_HANDLING

xml.parsers.expat.errors.XML_ERROR_NOT_STANDALONE

The parser determined that the document was not "standalone" though it declared itself to be in the XML declaration, and the **`NotStandaloneHandler`** was set and returned `0`.

xml.parsers.expat.errors.XML_ERROR_UNEXPECTED_STATE

xml.parsers.expat.errors.XML_ERROR_ENTITY_DECLARED_IN_PE

xml.parsers.expat.errors.XML_ERROR_FEATURE_REQUIRES_XML_DTD

An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the **`xml.parsers.expat`** module.

xml.parsers.expat.errors.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PAI

A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by **`UseForeignDTD()`**.

xml.parsers.expat.errors.XML_ERROR_UNBOUND_PREFIX

An undeclared prefix was found when namespace processing was enabled.

xml.parsers.expat.errors.XML_ERROR_UNDECLARING_PREFIX
: The document attempted to remove the namespace declaration associated with a prefix.

xml.parsers.expat.errors.XML_ERROR_INCOMPLETE_PE
: A parameter entity contained incomplete markup.

xml.parsers.expat.errors.XML_ERROR_XML_DECL
: The document contained no document element at all.

xml.parsers.expat.errors.XML_ERROR_TEXT_DECL
: There was an error parsing a text declaration in an external entity.

xml.parsers.expat.errors.XML_ERROR_PUBLICID
: Characters were found in the public id that are not allowed.

xml.parsers.expat.errors.XML_ERROR_SUSPENDED
: The requested operation was made on a suspended parser, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.errors.XML_ERROR_NOT_SUSPENDED
: An attempt to resume the parser was made when the parser had not been suspended.

xml.parsers.expat.errors.XML_ERROR_ABORTED
: This should not be reported to Python applications.

xml.parsers.expat.errors.XML_ERROR_FINISHED
: The requested operation was made on a parser which was finished parsing input, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.errors.XML_ERROR_SUSPEND_PE

xml.parsers.expat.errors.XML_ERROR_RESERVED_PREFIX_XML
: An attempt was made to undeclare reserved namespace prefix `xml` or to bind it to another namespace URI.

xml.parsers.expat.errors.XML_ERROR_RESERVED_PREFIX_XMLNS
: An attempt was made to declare or undeclare reserved namespace prefix `xmlns`.

xml.parsers.expat.errors.XML_ERROR_RESERVED_NAMESPACE_URI
: An attempt was made to bind the URI of one the reserved namespace prefixes `xml` and `xmlns` to another namespace prefix.

xml.parsers.expat.errors.XML_ERROR_INVALID_ARGUMENT
: This should not be reported to Python applications.

xml.parsers.expat.errors.XML_ERROR_NO_BUFFER
: This should not be reported to Python applications.

xml.parsers.expat.errors.XML_ERROR_AMPLIFICATION_LIMIT_BREACH
: The limit on input amplification factor (from DTD and entities) has been breached.

Footnotes

1
: The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

Internet Protocols and Support

The modules described in this chapter implement internet protocols and support for related technology. They are all implemented in Python. Most of these modules require the presence of the system-dependent module **socket**, which is currently supported on most popular platforms. Here is an overview:

- **webbrowser** — Convenient web-browser controller
  - Browser Controller Objects
- **wsgiref** — WSGI Utilities and Reference Implementation
  - **wsgiref.util** – WSGI environment utilities
  - **wsgiref.headers** – WSGI response header tools
  - **wsgiref.simple_server** – a simple WSGI HTTP server
  - **wsgiref.validate** — WSGI conformance checker
  - **wsgiref.handlers** – server/gateway base classes
  - **wsgiref.types** – WSGI types for static type checking
  - Examples
- **urllib** — URL handling modules
- **urllib.request** — Extensible library for opening URLs
  - Request Objects
  - OpenerDirector Objects
  - BaseHandler Objects
  - HTTPRedirectHandler Objects
  - HTTPCookieProcessor Objects
  - ProxyHandler Objects
  - HTTPPasswordMgr Objects
  - HTTPPasswordMgrWithPriorAuth Objects
  - AbstractBasicAuthHandler Objects
  - HTTPBasicAuthHandler Objects
  - ProxyBasicAuthHandler Objects

    - AbstractDigestAuthHandler Objects
    - HTTPDigestAuthHandler Objects
    - ProxyDigestAuthHandler Objects
    - HTTPHandler Objects
    - HTTPSHandler Objects
    - FileHandler Objects
    - DataHandler Objects
    - FTPHandler Objects
    - CacheFTPHandler Objects
    - UnknownHandler Objects
    - HTTPErrorProcessor Objects
    - Examples
    - Legacy interface
    - **`urllib.request`** Restrictions

- **`urllib.response`** — Response classes used by urllib
- **`urllib.parse`** — Parse URLs into components

    - URL Parsing
    - Parsing ASCII Encoded Bytes
    - Structured Parse Results
    - URL Quoting

- **`urllib.error`** — Exception classes raised by urllib.request
- **`urllib.robotparser`** — Parser for robots.txt
- **`http`** — HTTP modules

    - HTTP status codes
    - HTTP methods

- **`http.client`** — HTTP protocol client

    - HTTPConnection Objects
    - HTTPResponse Objects
    - Examples
    - HTTPMessage Objects

- **`ftplib`** — FTP protocol client

    - FTP Objects
    - FTP_TLS Objects

- **poplib** — POP3 protocol client
  - POP3 Objects
  - POP3 Example
- **imaplib** — IMAP4 protocol client
  - IMAP4 Objects
  - IMAP4 Example
- **smtplib** — SMTP protocol client
  - SMTP Objects
  - SMTP Example
- **uuid** — UUID objects according to **RFC 4122**
  - Example
- **socketserver** — A framework for network servers
  - Server Creation Notes
  - Server Objects
  - Request Handler Objects
  - Examples
    - **socketserver.TCPServer** Example
    - **socketserver.UDPServer** Example
    - Asynchronous Mixins
- **http.server** — HTTP servers
  - Security Considerations
- **http.cookies** — HTTP state management
  - Cookie Objects
  - Morsel Objects
  - Example
- **http.cookiejar** — Cookie handling for HTTP clients
  - CookieJar and FileCookieJar Objects

- FileCookieJar subclasses and co-operation with web browsers
- CookiePolicy Objects
- DefaultCookiePolicy Objects
- Cookie Objects
- Examples

- **xmlrpc** — XMLRPC server and client modules
- **xmlrpc.client** — XML-RPC client access
  - ServerProxy Objects
  - DateTime Objects
  - Binary Objects
  - Fault Objects
  - ProtocolError Objects
  - MultiCall Objects
  - Convenience Functions
  - Example of Client Usage
  - Example of Client and Server Usage
- **xmlrpc.server** — Basic XML-RPC servers
  - SimpleXMLRPCServer Objects
    - SimpleXMLRPCServer Example
  - CGIXMLRPCRequestHandler
  - Documenting XMLRPC server
  - DocXMLRPCServer Objects
  - DocCGIXMLRPCRequestHandler
- **ipaddress** — IPv4/IPv6 manipulation library
  - Convenience factory functions
  - IP Addresses
    - Address objects
    - Conversion to Strings and Integers
    - Operators
      - Comparison operators
      - Arithmetic operators

- IP Network definitions
  - Prefix, net mask and host mask
  - Network objects
  - Operators
    - Logical operators
    - Iteration
    - Networks as containers of addresses
- Interface objects
  - Operators
    - Logical operators
- Other Module Level Functions
- Custom Exceptions

`webbrowser` — Convenient web-browser controller

Source code: Lib/webbrowser.py [https://github.com/python/cpython/tree/3.11/Lib/webbrowser.py]

The `webbrowser` module provides a high-level interface to allow displaying web-based documents to users. Under most circumstances, simply calling the `open()` function from this module will do the right thing.

Under Unix, graphical browsers are preferred under X11, but text-mode browsers will be used if graphical browsers are not available or an X11 display isn't available. If text-mode browsers are used, the calling process will block until the user exits the browser.

If the environment variable `BROWSER` exists, it is interpreted as the `os.pathsep`-separated list of browsers to try ahead of the platform defaults. When the value of a list part contains the string `%s`, then it is interpreted as a literal browser command line to be used with the argument URL substituted for `%s`; if the part does not contain `%s`, it is simply interpreted as the name of the browser to launch. 1

For non-Unix platforms, or when a remote browser is available on Unix, the controlling process will not wait for the user to finish with the browser, but allow the remote browser to maintain its own windows on the display. If remote browsers are not available on Unix, the controlling process will launch a new browser and wait.

The script **webbrowser** can be used as a command-line interface for the module. It accepts a URL as the argument. It accepts the following optional parameters: `-n` opens the URL in a new browser window, if possible; `-t` opens the URL in a new browser page ("tab"). The options are, naturally, mutually exclusive. Usage example:

```
python -m webbrowser -t "https://www.python.org"
```

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The following exception is defined:

exception webbrowser.Error

Exception raised when a browser control error occurs.

The following functions are defined:

webbrowser.open(*url*, *new=0*, *autoraise=True*)

Display *url* using the default browser. If *new* is 0, the *url* is opened in the same browser window if possible. If *new* is 1, a new browser window is opened if possible. If *new* is 2, a new browser page ("tab") is opened if possible. If *autoraise* is `True`, the window is raised if possible (note that under many window managers this will occur regardless of the setting of this variable).

Note that on some platforms, trying to open a filename using this function, may work and start the operating system's associated program. However, this is neither supported nor portable.

Raises an auditing event `webbrowser.open` with argument `url`.

webbrowser.open_new(*url*)

Open *url* in a new window of the default browser, if possible, otherwise, open *url* in the only browser window.

webbrowser.open_new_tab(*url*)

Open *url* in a new page ("tab") of the default browser, if

possible, otherwise equivalent to `open_new()`.

webbrowser.get(*using=None*)

Return a controller object for the browser type *using*. If *using* is `None`, return a controller for a default browser appropriate to the caller's environment.

webbrowser.register(*name*, *constructor*, *instance=None*, ***, *preferred=False*)

Register the browser type *name*. Once a browser type is registered, the `get()` function can return a controller for that browser type. If *instance* is not provided, or is `None`, *constructor* will be called without parameters to create an instance when needed. If *instance* is provided, *constructor* will never be called, and may be `None`.

Setting *preferred* to `True` makes this browser a preferred result for a `get()` call with no argument. Otherwise, this entry point is only useful if you plan to either set the **BROWSER** variable or call `get()` with a nonempty argument matching the name of a handler you declare.

Changed in version 3.7: preferred keyword-only parameter was added.

A number of browser types are predefined. This table gives the type names that may be passed to the `get()` function and the corresponding instantiations for the controller classes, all defined in this module.

Type Name	Class Name
`'mozilla'`	`Mozilla('mozilla')`
`'firefox'`	`Mozilla('mozilla')`
`'netscape'`	`Mozilla('netscape')`
`'galeon'`	`Galeon('galeon')`
`'epiphany'`	`Galeon('epiphany')`
`'skipstone'`	`BackgroundBrowser('skipstone')`
`'kfmclient'`	`Konqueror()`
`'konqueror'`	`Konqueror()`

(1)	`Konqueror()`
	`BackgroundBrowser('mosaic')`
	`Opera()`
	`Grail()`
	`GenericBrowser('links')`
	`Elinks('elinks')`
	`GenericBrowser('lynx')`
	`GenericBrowser('w3m')`
(2)	`WindowsDefault`
(3)	`MacOSXOSAScript('default')`
(3)	`MacOSXOSAScript('safari')`
	`Chrome('google-chrome')`
	`Chrome('chrome')`
	`Chromium('chromium')`
	`Chromium('chromium-browser')`

Notes:

1. “Konqueror” is the file manager for the KDE desktop environment for Unix, and only makes sense to use if KDE is running. Some way of reliably detecting KDE would be nice; the **KDEDIR** variable is not sufficient. Note also that the name “kfm” is used even when using the **konqueror** command with KDE 2 — the implementation selects the best strategy for running Konqueror.
2. Only on Windows platforms.
3. Only on macOS platform.

New in version 3.3: Support for Chrome/Chromium has been added.

Deprecated since version 3.11, will be removed in version 3.13: **MacOSX** is deprecated, use **MacOSXOSAScript** instead.

Here are some simple examples:

```
url = 'https://docs.python.org/'

# Open URL in a new tab, if a browser window is already
webbrowser.open_new_tab(url)

# Open URL in new window, raising the window if possible
```

```
webbrowser.open_new(url)
```

Browser Controller Objects

Browser controllers provide these methods which parallel three of the module-level convenience functions:

webbrowser.name

System-dependent name for the browser.

controller.open(*url*, *new* = *0*, *autoraise* = *True*)

Display *url* using the browser handled by this controller. If *new* is 1, a new browser window is opened if possible. If *new* is 2, a new browser page (“tab”) is opened if possible.

controller.open_new(*url*)

Open *url* in a new window of the browser handled by this controller, if possible, otherwise, open *url* in the only browser window. Alias **`open_new()`**.

controller.open_new_tab(*url*)

Open *url* in a new page (“tab”) of the browser handled by this controller, if possible, otherwise equivalent to **`open_new()`**.

Footnotes

1

Executables named here without a full path will be searched in the directories given in the **`PATH`** environment variable.

`wsgiref` — WSGI Utilities and Reference Implementation

Source code: Lib/wsgiref [https://github.com/python/cpython/tree/3.11/Lib/wsgiref]

The Web Server Gateway Interface (WSGI) is a standard interface between web server software and web applications written in Python. Having a standard interface makes it easy to use an application that supports WSGI with a number of different web servers.

Only authors of web servers and programming frameworks need to know every detail and corner case of the WSGI design. You don't need to understand every detail of WSGI just to install a WSGI application or to write a web application using an existing framework.

`wsgiref` is a reference implementation of the WSGI specification that can be used to add WSGI support to a web server or framework. It provides utilities for manipulating WSGI environment variables and response headers, base classes for implementing WSGI servers, a demo HTTP server that serves WSGI applications, types for static type checking, and a validation tool that checks WSGI servers and applications for conformance to the WSGI specification (**PEP 3333** [https://peps.python.org/pep-3333/]).

See wsgi.readthedocs.io [https://wsgi.readthedocs.io/] for more information about WSGI, and links to tutorials and other resources.

`wsgiref.util` – WSGI environment utilities

This module provides a variety of utility functions for working with

WSGI environments. A WSGI environment is a dictionary containing HTTP request variables as described in **PEP 3333** [https://peps.python.org/pep-3333/]. All of the functions taking an *environ* parameter expect a WSGI-compliant dictionary to be supplied; please see **PEP 3333** [https://peps.python.org/pep-3333/] for a detailed specification and **`WSGIEnvironment`** for a type alias that can be used in type annotations.

wsgiref.util.guess_scheme(*environ*)

Return a guess for whether `wsgi.url_scheme` should be "http" or "https", by checking for a `HTTPS` environment variable in the *environ* dictionary. The return value is a string.

This function is useful when creating a gateway that wraps CGI or a CGI-like protocol such as FastCGI. Typically, servers providing such protocols will include a `HTTPS` variable with a value of "1", "yes", or "on" when a request is received via SSL. So, this function returns "https" if such a value is found, and "http" otherwise.

wsgiref.util.request_uri(*environ*, *include_query=True*)

Return the full request URI, optionally including the query string, using the algorithm found in the "URL Reconstruction" section of **PEP 3333** [https://peps.python.org/pep-3333/]. If *include_query* is false, the query string is not included in the resulting URI.

wsgiref.util.application_uri(*environ*)

Similar to **`request_uri()`**, except that the `PATH_INFO` and `QUERY_STRING` variables are ignored. The result is the base URI of the application object addressed by the request.

wsgiref.util.shift_path_info(*environ*)

Shift a single name from `PATH_INFO` to `SCRIPT_NAME` and return the name. The *environ* dictionary is *modified* in-place; use a copy if you need to keep the original `PATH_INFO` or `SCRIPT_NAME` intact.

If there are no remaining path segments in `PATH_INFO`, `None` is returned.

Typically, this routine is used to process each portion of a request URI path, for example to treat the path as a series of dictionary keys. This routine modifies the passed-in environment to make it suitable for invoking another WSGI application that is located at the target URI. For example, if there is a WSGI application at `/foo`, and the request URI path is `/foo/bar/baz`, and the WSGI application at `/foo` calls **`shift_path_info()`**, it will receive the string "bar", and the environment will be updated to be suitable for passing to a WSGI application at `/foo/bar`. That is, `SCRIPT_NAME` will change from `/foo` to `/foo/bar`, and `PATH_INFO` will change from `/bar/baz` to `/baz`.

When `PATH_INFO` is just a "/", this routine returns an empty string and appends a trailing slash to `SCRIPT_NAME`, even though empty path segments are normally ignored, and `SCRIPT_NAME` doesn't normally end in a slash. This is intentional behavior, to ensure that an application can tell the difference between URIs ending in `/x` from ones ending in `/x/` when using this routine to do object traversal.

wsgiref.util.setup_testing_defaults(*environ*)

Update *environ* with trivial defaults for testing purposes.

This routine adds various parameters required for WSGI, including `HTTP_HOST`, `SERVER_NAME`, `SERVER_PORT`, `REQUEST_METHOD`, `SCRIPT_NAME`, `PATH_INFO`, and all of the **PEP 3333** [https://peps.python.org/pep-3333/]-defined `wsgi.*` variables. It only supplies default values, and does not replace any existing settings for these variables.

This routine is intended to make it easier for unit tests of WSGI servers and applications to set up dummy environments. It should NOT be used by actual WSGI servers or applications, since the data is fake!

Example usage:

```
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server

# A relatively simple WSGI application. It's going
# environment dictionary after being updated by set
def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain; charse

    start_response(status, headers)

    ret = [("%s: %s\n" % (key, value)).encode("utf-
           for key, value in environ.items()]
    return ret

with make_server('', 8000, simple_app) as httpd:
    print("Serving on port 8000...")
    httpd.serve_forever()
```

In addition to the environment functions above, the **`wsgiref.util`** module also provides these miscellaneous utilities:

wsgiref.util.is_hop_by_hop(*header_name*)

Return `True` if 'header_name' is an HTTP/1.1 "Hop-by-Hop" header, as defined by **RFC 2616** [https://datatracker.ietf.org/doc/html/rfc2616.html].

class wsgiref.util.FileWrapper(*filelike*, *blksize=8192*)

A concrete implementation of the **`wsgiref.types.FileWrapper`** protocol used to convert a file-like object to an iterator. The resulting objects are iterables. As the object is iterated over, the optional *blksize* parameter will be repeatedly passed to the *filelike* object's **`read()`** method to obtain bytestrings to yield. When **`read()`** returns an empty bytestring, iteration is ended and is not resumable.

If *filelike* has a **close()** method, the returned object will also have a **close()** method, and it will invoke the *filelike* object's **close()** method when called.

Example usage:

```
from io import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-lik
filelike = StringIO("This is an example file-like o
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print(chunk)
```

Changed in version 3.11: Support for **__getitem__()** method has been removed.

wsgiref.headers – WSGI response header tools

This module provides a single class, **Headers**, for convenient manipulation of WSGI response headers using a mapping-like interface.

class wsgiref.headers.Headers([*headers*])

Create a mapping-like object wrapping *headers*, which must be a list of header name/value tuples as described in **PEP 3333** [https://peps.python.org/pep-3333/]. The default value of *headers* is an empty list.

Headers objects support typical mapping operations including **__getitem__()**, **get()**, **__setitem__()**, **setdefault()**, **__delitem__()** and **__contains__()**. For each of these methods, the key is the header name (treated case-insensitively), and the value is the first value associated with that header name. Setting a header deletes any existing values for that header, then adds a new value at

the end of the wrapped header list. Headers' existing order is generally maintained, with new headers added to the end of the wrapped list.

Unlike a dictionary, **Headers** objects do not raise an error when you try to get or delete a key that isn't in the wrapped header list. Getting a nonexistent header just returns `None`, and deleting a nonexistent header does nothing.

Headers objects also support **keys()**, **values()**, and **items()** methods. The lists returned by **keys()** and **items()** can include the same key more than once if there is a multi-valued header. The `len()` of a **Headers** object is the same as the length of its **items()**, which is the same as the length of the wrapped header list. In fact, the **items()** method just returns a copy of the wrapped header list.

Calling `bytes()` on a **Headers** object returns a formatted bytestring suitable for transmission as HTTP response headers. Each header is placed on a line with its value, separated by a colon and a space. Each line is terminated by a carriage return and line feed, and the bytestring is terminated with a blank line.

In addition to their mapping interface and formatting features, **Headers** objects also have the following methods for querying and adding multi-valued headers, and for adding headers with MIME parameters:

get_all(*name*)

> Return a list of all the values for the named header.
>
> The returned list will be sorted in the order they appeared in the original header list or were added to this instance, and may contain duplicates. Any fields deleted and re-inserted are always appended to the header list. If no fields exist with the given name, returns an empty list.

add_header(*name*, *value*, ***_params*)

Add a (possibly multi-valued) header, with optional MIME parameters specified via keyword arguments.

name is the header field to add. Keyword arguments can be used to set MIME parameters for the header field. Each parameter must be a string or `None`. Underscores in parameter names are converted to dashes, since dashes are illegal in Python identifiers, but many MIME parameter names include dashes. If the parameter value is a string, it is added to the header value parameters in the form `name="value"`. If it is `None`, only the parameter name is added. (This is used for MIME parameters without a value.) Example usage:

```
h.add_header('content-disposition', 'attachment
```

The above will add a header that looks like this:

```
Content-Disposition: attachment; filename="bud.
```

Changed in version 3.5: headers parameter is optional.

`wsgiref.simple_server` – a simple WSGI HTTP server

This module implements a simple HTTP server (based on `http.server`) that serves WSGI applications. Each server instance serves a single WSGI application on a given host and port. If you want to serve multiple applications on a single host and port, you should create a WSGI application that parses `PATH_INFO` to select which application to invoke for each request. (E.g., using the **`shift_path_info()`** function from `wsgiref.util`.)

wsgiref.simple_server.make_server(*host*, *port*, *app*, *server_class*=*WSGIServer*, *handler_class*=*WSGIRequestHandler*)

Create a new WSGI server listening on *host* and *port*, accepting connections for *app*. The return value is an instance of the supplied *server_class*, and will process requests using the specified *handler_class*. *app* must be a WSGI application object,

as defined by **PEP 3333** [https://peps.python.org/pep-3333/].

Example usage:

```
from wsgiref.simple_server import make_server, demo

with make_server('', 8000, demo_app) as httpd:
    print("Serving HTTP on port 8000...")

    # Respond to requests until process is killed
    httpd.serve_forever()

    # Alternative: serve one request, then exit
    httpd.handle_request()
```

wsgiref.simple_server.demo_app(*environ*, *start_response*)

This function is a small but complete WSGI application that returns a text page containing the message "Hello world!" and a list of the key/value pairs provided in the *environ* parameter. It's useful for verifying that a WSGI server (such as **wsgiref.simple_server**) is able to run a simple WSGI application correctly.

class wsgiref.simple_server.WSGIServer(*server_address*, *RequestHandlerClass*)

Create a **WSGIServer** instance. *server_address* should be a `(host,port)` tuple, and *RequestHandlerClass* should be the subclass of **http.server.BaseHTTPRequestHandler** that will be used to process requests.

You do not normally need to call this constructor, as the **make_server()** function can handle all the details for you.

WSGIServer is a subclass of **http.server.HTTPServer**, so all of its methods (such as **serve_forever()** and **handle_request()**) are available. **WSGIServer** also provides these WSGI-specific methods:

set_app(*application*)

Sets the callable *application* as the WSGI application that will receive requests.

get_app()

Returns the currently set application callable.

Normally, however, you do not need to use these additional methods, as **`set_app()`** is normally called by **`make_server()`**, and the **`get_app()`** exists mainly for the benefit of request handler instances.

class wsgiref.simple_server.WSGIRequestHandler(*request*, *client_address*, *server*)

Create an HTTP handler for the given *request* (i.e. a socket), *client_address* (a `(host,port)` tuple), and *server* (**`WSGIServer`** instance).

You do not need to create instances of this class directly; they are automatically created as needed by **`WSGIServer`** objects. You can, however, subclass this class and supply it as a *handler_class* to the **`make_server()`** function. Some possibly relevant methods for overriding in subclasses:

get_environ()

Return a **`WSGIEnvironment`** dictionary for a request. The default implementation copies the contents of the **`WSGIServer`** object's **`base_environ`** dictionary attribute and then adds various headers derived from the HTTP request. Each call to this method should return a new dictionary containing all of the relevant CGI environment variables as specified in **PEP 3333** [https://peps.python.org/pep-3333/].

get_stderr()

Return the object that should be used as the `wsgi.errors` stream. The default implementation just returns `sys.stderr`.

handle()

Process the HTTP request. The default implementation creates a handler instance using a **wsgiref.handlers** class to implement the actual WSGI application interface.

wsgiref.validate — WSGI conformance checker

When creating new WSGI application objects, frameworks, servers, or middleware, it can be useful to validate the new code's conformance using **wsgiref.validate**. This module provides a function that creates WSGI application objects that validate communications between a WSGI server or gateway and a WSGI application object, to check both sides for protocol conformance.

Note that this utility does not guarantee complete **PEP 3333** [https://peps.python.org/pep-3333/] compliance; an absence of errors from this module does not necessarily mean that errors do not exist. However, if this module does produce an error, then it is virtually certain that either the server or application is not 100% compliant.

This module is based on the **paste.lint** module from Ian Bicking's "Python Paste" library.

wsgiref.validate.validator(*application*)

Wrap *application* and return a new WSGI application object. The returned application will forward all requests to the original *application*, and will check that both the *application* and the server invoking it are conforming to the WSGI specification and to **RFC 2616** [https://datatracker.ietf.org/doc/html/rfc2616.html].

Any detected nonconformance results in an **AssertionError** being raised; note, however, that how these errors are handled is server-dependent. For example, **wsgiref.simple_server** and other servers based on **wsgiref.handlers** (that don't override the error handling methods to do something else) will simply output a message

that an error has occurred, and dump the traceback to `sys.stderr` or some other error stream.

This wrapper may also generate output using the **`warnings`** module to indicate behaviors that are questionable but which may not actually be prohibited by **PEP 3333** [https://peps.python.org/pep-3333/]. Unless they are suppressed using Python command-line options or the **`warnings`** API, any such warnings will be written to `sys.stderr` (*not* `wsgi.errors`, unless they happen to be the same object).

Example usage:

```
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

# Our callable object which is intentionally not co
# standard, so the validator is going to break
def simple_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # H
    start_response(status, headers)

    # This is going to break because we need to ret
    # the validator is going to inform us
    return b"Hello World"

# This is the application wrapped in a validator
validator_app = validator(simple_app)

with make_server('', 8000, validator_app) as httpd:
    print("Listening on port 8000....")
    httpd.serve_forever()
```

`wsgiref.handlers` – server/gateway base classes

This module provides base handler classes for implementing WSGI

servers and gateways. These base classes handle most of the work of communicating with a WSGI application, as long as they are given a CGI-like environment, along with input, output, and error streams.

class wsgiref.handlers.CGIHandler

CGI-based invocation via `sys.stdin`, `sys.stdout`, `sys.stderr` and `os.environ`. This is useful when you have a WSGI application and want to run it as a CGI script. Simply invoke `CGIHandler().run(app)`, where `app` is the WSGI application object you wish to invoke.

This class is a subclass of **`BaseCGIHandler`** that sets `wsgi.run_once` to true, `wsgi.multithread` to false, and `wsgi.multiprocess` to true, and always uses **`sys`** and **`os`** to obtain the necessary CGI streams and environment.

class wsgiref.handlers.IISCGIHandler

A specialized alternative to **`CGIHandler`**, for use when deploying on Microsoft's IIS web server, without having set the config allowPathInfo option (IIS>=7) or metabase allowPathInfoForScriptMappings (IIS<7).

By default, IIS gives a `PATH_INFO` that duplicates the `SCRIPT_NAME` at the front, causing problems for WSGI applications that wish to implement routing. This handler strips any such duplicated path.

IIS can be configured to pass the correct `PATH_INFO`, but this causes another bug where `PATH_TRANSLATED` is wrong. Luckily this variable is rarely used and is not guaranteed by WSGI. On IIS<7, though, the setting can only be made on a vhost level, affecting all other script mappings, many of which break when exposed to the `PATH_TRANSLATED` bug. For this reason IIS<7 is almost never deployed with the fix (Even IIS7 rarely uses it because there is still no UI for it.).

There is no way for CGI code to tell whether the option was set, so a separate handler class is provided. It is used in the same way as **`CGIHandler`**, i.e., by calling `IISCGIHandler().run(app)`, where `app` is the WSGI

application object you wish to invoke.

New in version 3.2.

class wsgiref.handlers.BaseCGIHandler(*stdin*, *stdout*, *stderr*, *environ*, *multithread=True*, *multiprocess=False*)

Similar to **CGIHandler**, but instead of using the **sys** and **os** modules, the CGI environment and I/O streams are specified explicitly. The *multithread* and *multiprocess* values are used to set the `wsgi.multithread` and `wsgi.multiprocess` flags for any applications run by the handler instance.

This class is a subclass of **SimpleHandler** intended for use with software other than HTTP "origin servers". If you are writing a gateway protocol implementation (such as CGI, FastCGI, SCGI, etc.) that uses a `Status:` header to send an HTTP status, you probably want to subclass this instead of **SimpleHandler**.

class wsgiref.handlers.SimpleHandler(*stdin*, *stdout*, *stderr*, *environ*, *multithread=True*, *multiprocess=False*)

Similar to **BaseCGIHandler**, but designed for use with HTTP origin servers. If you are writing an HTTP server implementation, you will probably want to subclass this instead of **BaseCGIHandler**.

This class is a subclass of **BaseHandler**. It overrides the **__init__()**, **get_stdin()**, **get_stderr()**, **add_cgi_vars()**, **_write()**, and **_flush()** methods to support explicitly setting the environment and streams via the constructor. The supplied environment and streams are stored in the **stdin**, **stdout**, **stderr**, and **environ** attributes.

The **write()** method of *stdout* should write each chunk in full, like **io.BufferedIOBase**.

class wsgiref.handlers.BaseHandler

This is an abstract base class for running WSGI applications.

Each instance will handle a single HTTP request, although in principle you could create a subclass that was reusable for multiple requests.

BaseHandler instances have only one method intended for external use:

run(*app*)

Run the specified WSGI application, *app*.

All of the other **BaseHandler** methods are invoked by this method in the process of running the application, and thus exist primarily to allow customizing the process.

The following methods MUST be overridden in a subclass:

_write(*data*)

Buffer the bytes *data* for transmission to the client. It's okay if this method actually transmits the data; **BaseHandler** just separates write and flush operations for greater efficiency when the underlying system actually has such a distinction.

_flush()

Force buffered data to be transmitted to the client. It's okay if this method is a no-op (i.e., if **_write()** actually sends the data).

get_stdin()

Return an object compatible with **InputStream** suitable for use as the `wsgi.input` of the request currently being processed.

get_stderr()

Return an object compatible with **ErrorStream** suitable for use as the `wsgi.errors` of the request currently being processed.

add_cgi_vars()

Insert CGI variables for the current request into the **`environ`** attribute.

Here are some other methods and attributes you may wish to override. This list is only a summary, however, and does not include every method that can be overridden. You should consult the docstrings and source code for additional information before attempting to create a customized **`BaseHandler`** subclass.

Attributes and methods for customizing the WSGI environment:

wsgi_multithread

The value to be used for the `wsgi.multithread` environment variable. It defaults to true in **`BaseHandler`**, but may have a different default (or be set by the constructor) in the other subclasses.

wsgi_multiprocess

The value to be used for the `wsgi.multiprocess` environment variable. It defaults to true in **`BaseHandler`**, but may have a different default (or be set by the constructor) in the other subclasses.

wsgi_run_once

The value to be used for the `wsgi.run_once` environment variable. It defaults to false in **`BaseHandler`**, but **`CGIHandler`** sets it to true by default.

os_environ

The default environment variables to be included in every request's WSGI environment. By default, this is a copy of `os.environ` at the time that **`wsgiref.handlers`** was imported, but subclasses can either create their own at the class or instance level.

Note that the dictionary should be considered read-only, since the default value is shared between multiple classes and instances.

server_software

If the **origin_server** attribute is set, this attribute's value is used to set the default `SERVER_SOFTWARE` WSGI environment variable, and also to set a default `Server:` header in HTTP responses. It is ignored for handlers (such as **BaseCGIHandler** and **CGIHandler**) that are not HTTP origin servers.

Changed in version 3.3: The term "Python" is replaced with implementation specific term like "CPython", "Jython" etc.

get_scheme()

Return the URL scheme being used for the current request. The default implementation uses the **guess_scheme()** function from **wsgiref.util** to guess whether the scheme should be "http" or "https", based on the current request's **environ** variables.

setup_environ()

Set the **environ** attribute to a fully populated WSGI environment. The default implementation uses all of the above methods and attributes, plus the **get_stdin()**, **get_stderr()**, and **add_cgi_vars()** methods and the **wsgi_file_wrapper** attribute. It also inserts a `SERVER_SOFTWARE` key if not present, as long as the **origin_server** attribute is a true value and the **server_software** attribute is set.

Methods and attributes for customizing exception handling:

log_exception(*exc_info*)

Log the *exc_info* tuple in the server log. *exc_info* is a

`(type, value, traceback)` tuple. The default implementation simply writes the traceback to the request's `wsgi.errors` stream and flushes it. Subclasses can override this method to change the format or retarget the output, mail the traceback to an administrator, or whatever other action may be deemed suitable.

traceback_limit

The maximum number of frames to include in tracebacks output by the default **`log_exception()`** method. If `None`, all frames are included.

error_output(*environ*, *start_response*)

This method is a WSGI application to generate an error page for the user. It is only invoked if an error occurs before headers are sent to the client.

This method can access the current error information using `sys.exc_info()`, and should pass that information to *start_response* when calling it (as described in the "Error Handling" section of **PEP 3333** [https://peps.python.org/pep-3333/]).

The default implementation just uses the **`error_status`**, **`error_headers`**, and **`error_body`** attributes to generate an output page. Subclasses can override this to produce more dynamic error output.

Note, however, that it's not recommended from a security perspective to spit out diagnostics to any old user; ideally, you should have to do something special to enable diagnostic output, which is why the default implementation doesn't include any.

error_status

The HTTP status used for error responses. This should be a status string as defined in **PEP 3333** [https://peps.python.org/pep-3333/]; it defaults to a 500 code and

message.

error_headers

The HTTP headers used for error responses. This should be a list of WSGI response headers (`(name, value)` tuples), as described in **PEP 3333** [https://peps.python.org/pep-3333/]. The default list just sets the content type to `text/plain`.

error_body

The error response body. This should be an HTTP response body bytestring. It defaults to the plain text, "A server error occurred. Please contact the administrator."

Methods and attributes for **PEP 3333** [https://peps.python.org/pep-3333/]'s "Optional Platform-Specific File Handling" feature:

wsgi_file_wrapper

A `wsgi.file_wrapper` factory, compatible with **`wsgiref.types.FileWrapper`**, or `None`. The default value of this attribute is the **`wsgiref.util.FileWrapper`** class.

sendfile()

Override to implement platform-specific file transmission. This method is called only if the application's return value is an instance of the class specified by the **`wsgi_file_wrapper`** attribute. It should return a true value if it was able to successfully transmit the file, so that the default transmission code will not be executed. The default implementation of this method just returns a false value.

Miscellaneous methods and attributes:

origin_server

This attribute should be set to a true value if the

handler's **_write()** and **_flush()** are being used to communicate directly to the client, rather than via a CGI-like gateway protocol that wants the HTTP status in a special `Status:` header.

This attribute's default value is true in **BaseHandler**, but false in **BaseCGIHandler** and **CGIHandler**.

http_version

If **origin_server** is true, this string attribute is used to set the HTTP version of the response set to the client. It defaults to `"1.0"`.

wsgiref.handlers.read_environ()

Transcode CGI variables from `os.environ` to **PEP 3333** [https://peps.python.org/pep-3333/] "bytes in unicode" strings, returning a new dictionary. This function is used by **CGIHandler** and **IISCGIHandler** in place of directly using `os.environ`, which is not necessarily WSGI-compliant on all platforms and web servers using Python 3 – specifically, ones where the OS's actual environment is Unicode (i.e. Windows), or ones where the environment is bytes, but the system encoding used by Python to decode it is anything other than ISO-8859-1 (e.g. Unix systems using UTF-8).

If you are implementing a CGI-based handler of your own, you probably want to use this routine instead of just copying values out of `os.environ` directly.

New in version 3.2.

wsgiref.types – WSGI types for static type checking

This module provides various types for static type checking as described in **PEP 3333** [https://peps.python.org/pep-3333/].

New in version 3.11.

class wsgiref.types.StartResponse

A **typing.Protocol** describing start_response() [https://peps.python.org/pep-3333/#the-start-response-callable] callables (**PEP 3333** [https://peps.python.org/pep-3333/]).

wsgiref.types.WSGIEnvironment

A type alias describing a WSGI environment dictionary.

wsgiref.types.WSGIApplication

A type alias describing a WSGI application callable.

class wsgiref.types.InputStream

A **typing.Protocol** describing a WSGI Input Stream [https://peps.python.org/pep-3333/#input-and-error-streams].

class wsgiref.types.ErrorStream

A **typing.Protocol** describing a WSGI Error Stream [https://peps.python.org/pep-3333/#input-and-error-streams].

class wsgiref.types.FileWrapper

A **typing.Protocol** describing a file wrapper [https://peps.python.org/pep-3333/#optional-platform-specific-file-handling]. See **wsgiref.util.FileWrapper** for a concrete implementation of this protocol.

Examples

This is a working “Hello World” WSGI application:

```
"""
Every WSGI application must have an application object -
object that accepts two arguments. For that purpose, we'
use a function (note that you're not limited to a functi
use a class for example). The first argument passed to t
is a dictionary containing CGI-style environment variabl
second variable is the callable object.
"""
```

```
from wsgiref.simple_server import make_server

def hello_world_app(environ, start_response):
    status = "200 OK"  # HTTP Status
    headers = [("Content-type", "text/plain; charset=utf
    start_response(status, headers)

    # The returned object is going to be printed
    return [b"Hello World"]

with make_server("", 8000, hello_world_app) as httpd:
    print("Serving on port 8000...")

    # Serve until process is killed
    httpd.serve_forever()
```

Example of a WSGI application serving the current directory, accept optional directory and port number (default: 8000) on the command line:

```
"""
Small wsgiref based web server. Takes a path to serve fr
optional port number (defaults to 8000), then tries to s
MIME types are guessed from the file names, 404 errors a
if the file is not found.
"""
import mimetypes
import os
import sys
from wsgiref import simple_server, util

def app(environ, respond):
    # Get the file name and MIME type
    fn = os.path.join(path, environ["PATH_INFO"][1:])
    if "." not in fn.split(os.path.sep)[-1]:
        fn = os.path.join(fn, "index.html")
    mime_type = mimetypes.guess_type(fn)[0]
```

```
    # Return 200 OK if file exists, otherwise 404 Not Fo
    if os.path.exists(fn):
        respond("200 OK", [("Content-Type", mime_type)])
        return util.FileWrapper(open(fn, "rb"))
    else:
        respond("404 Not Found", [("Content-Type", "text
        return [b"not found"]

if __name__ == "__main__":
    # Get the path and port from command-line arguments
    path = sys.argv[1] if len(sys.argv) > 1 else os.getc
    port = int(sys.argv[2]) if len(sys.argv) > 2 else 80

    # Make and start the server until control-c
    httpd = simple_server.make_server("", port, app)
    print(f"Serving {path} on port {port}, control-C to
    try:
        httpd.serve_forever()
    except KeyboardInterrupt:
        print("Shutting down.")
        httpd.server_close()
```

`urllib` — URL handling modules

Source code: Lib/urllib/ [https://github.com/python/cpython/tree/3.11/Lib/urllib/]

`urllib` is a package that collects several modules for working with URLs:

- **`urllib.request`** for opening and reading URLs
- **`urllib.error`** containing the exceptions raised by **`urllib.request`**
- **`urllib.parse`** for parsing URLs
- **`urllib.robotparser`** for parsing `robots.txt` files

`urllib.request` — Extensible library for opening URLs

Source code: Lib/urllib/request.py [https://github.com/python/cpython/tree/3.11/Lib/urllib/request.py]

The `urllib.request` module defines functions and classes which help in opening URLs (mostly HTTP) in a complex world — basic and digest authentication, redirections, cookies and more.

See also

The Requests package [https://requests.readthedocs.io/en/master/] is recommended for a higher-level HTTP client interface.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The `urllib.request` module defines the following functions:

urllib.request.urlopen(*url*, *data*=*None*, [*timeout*,]*, *cafile*=*None*, *capath*=*None*, *cadefault*=*False*, *context*=*None*)

Open the URL *url*, which can be either a string or a `Request` object.

data must be an object specifying additional data to be sent to the server, or `None` if no such data is needed. See `Request` for details.

urllib.request module uses HTTP/1.1 and includes

`Connection:close` header in its HTTP requests.

The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). This actually only works for HTTP, HTTPS and FTP connections.

If *context* is specified, it must be a **`ssl.SSLContext`** instance describing the various SSL options. See **`HTTPSConnection`** for more details.

The optional *cafile* and *capath* parameters specify a set of trusted CA certificates for HTTPS requests. *cafile* should point to a single file containing a bundle of CA certificates, whereas *capath* should point to a directory of hashed certificate files. More information can be found in **`ssl.SSLContext.load_verify_locations()`**.

The *cadefault* parameter is ignored.

This function always returns an object which can work as a context manager and has the properties *url*, *headers*, and *status*. See **`urllib.response.addinfourl`** for more detail on these properties.

For HTTP and HTTPS URLs, this function returns a **`http.client.HTTPResponse`** object slightly modified. In addition to the three new methods above, the msg attribute contains the same information as the **`reason`** attribute — the reason phrase returned by server — instead of the response headers as it is specified in the documentation for **`HTTPResponse`**.

For FTP, file, and data URLs and requests explicitly handled by legacy **`URLopener`** and **`FancyURLopener`** classes, this function returns a **`urllib.response.addinfourl`** object.

Raises **`URLError`** on protocol errors.

Note that `None` may be returned if no handler handles the

request (though the default installed global **OpenerDirector** uses **UnknownHandler** to ensure this never happens).

In addition, if proxy settings are detected (for example, when a `*_proxy` environment variable like **http_proxy** is set), **ProxyHandler** is default installed and makes sure the requests are handled through the proxy.

The legacy `urllib.urlopen` function from Python 2.6 and earlier has been discontinued; **urllib.request.urlopen()** corresponds to the old `urllib2.urlopen`. Proxy handling, which was done by passing a dictionary parameter to `urllib.urlopen`, can be obtained by using **ProxyHandler** objects.

The default opener raises an auditing event `urllib.Request` with arguments `fullurl`, `data`, `headers`, `method` taken from the request object.

Changed in version 3.2: cafile and *capath* were added.

Changed in version 3.2: HTTPS virtual hosts are now supported if possible (that is, if **ssl.HAS_SNI** is true).

New in version 3.2: data can be an iterable object.

Changed in version 3.3: cadefault was added.

Changed in version 3.4.3: context was added.

Changed in version 3.10: HTTPS connection now send an ALPN extension with protocol indicator `http/1.1` when no *context* is given. Custom *context* should set ALPN protocols with **set_alpn_protocol()**.

Deprecated since version 3.6: cafile, *capath* and *cadefault* are deprecated in favor of *context*. Please use **ssl.SSLContext.load_cert_chain()** instead, or let **ssl.create_default_context()** select the system's

trusted CA certificates for you.

urllib.request.install_opener(*opener*)

Install an **OpenerDirector** instance as the default global opener. Installing an opener is only necessary if you want urlopen to use that opener; otherwise, simply call **OpenerDirector.open()** instead of **urlopen()**. The code does not check for a real **OpenerDirector**, and any class with the appropriate interface will work.

urllib.request.build_opener([*handler*, ...])

Return an **OpenerDirector** instance, which chains the handlers in the order given. *handler*s can be either instances of **BaseHandler**, or subclasses of **BaseHandler** (in which case it must be possible to call the constructor without any parameters). Instances of the following classes will be in front of the *handler*s, unless the *handler*s contain them, instances of them or subclasses of them: **ProxyHandler** (if proxy settings are detected), **UnknownHandler**, **HTTPHandler**, **HTTPDefaultErrorHandler**, **HTTPRedirectHandler**, **FTPHandler**, **FileHandler**, **HTTPErrorProcessor**.

If the Python installation has SSL support (i.e., if the **ssl** module can be imported), **HTTPSHandler** will also be added.

A **BaseHandler** subclass may also change its **handler_order** attribute to modify its position in the handlers list.

urllib.request.pathname2url(*path*)

Convert the pathname *path* from the local syntax for a path to the form used in the path component of a URL. This does not produce a complete URL. The return value will already be quoted using the **quote()** function.

urllib.request.url2pathname(*path*)

Convert the path component *path* from a percent-encoded

URL to the local syntax for a path. This does not accept a complete URL. This function uses `unquote()` to decode *path*.

urllib.request.getproxies()

This helper function returns a dictionary of scheme to proxy server URL mappings. It scans the environment for variables named `<scheme>_proxy`, in a case insensitive approach, for all operating systems first, and when it cannot find it, looks for proxy information from System Configuration for macOS and Windows Systems Registry for Windows. If both lowercase and uppercase environment variables exist (and disagree), lowercase is preferred.

Note

If the environment variable `REQUEST_METHOD` is set, which usually indicates your script is running in a CGI environment, the environment variable `HTTP_PROXY` (uppercase `_PROXY`) will be ignored. This is because that variable can be injected by a client using the "Proxy:" HTTP header. If you need to use an HTTP proxy in a CGI environment, either use `ProxyHandler` explicitly, or make sure the variable name is in lowercase (or at least the `_proxy` suffix).

The following classes are provided:

class urllib.request.Request(*url*, *data*=*None*, *headers*={}, *origin_req_host*=*None*, *unverifiable*=*False*, *method*=*None*)

This class is an abstraction of a URL request.

url should be a string containing a valid URL.

data must be an object specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use *data*. The supported object types include bytes, file-like objects, and iterables of

bytes-like objects. If no `Content-Length` nor `Transfer-Encoding` header field has been provided, **`HTTPHandler`** will set these headers according to the type of *data*. `Content-Length` will be used to send bytes objects, while `Transfer-Encoding: chunked` as specified in **RFC 7230** [https://datatracker.ietf.org/doc/html/rfc7230.html], Section 3.3.1 will be used to send files and other iterables.

For an HTTP POST request method, *data* should be a buffer in the standard *application/x-www-form-urlencoded* format. The **`urllib.parse.urlencode()`** function takes a mapping or sequence of 2-tuples and returns an ASCII string in this format. It should be encoded to bytes before being used as the *data* parameter.

headers should be a dictionary, and will be treated as if **`add_header()`** was called with each key and value as arguments. This is often used to "spoof" the `User-Agent` header value, which is used by a browser to identify itself – some HTTP servers only allow requests coming from common browsers as opposed to scripts. For example, Mozilla Firefox may identify itself as `"Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11"`, while **`urllib`**'s default user agent string is `"Python-urllib/2.6"` (on Python 2.6). All header keys are sent in camel case.

An appropriate `Content-Type` header should be included if the *data* argument is present. If this header has not been provided and *data* is not None, `Content-Type: application/x-www-form-urlencoded` will be added as a default.

The next two arguments are only of interest for correct handling of third-party HTTP cookies:

origin_req_host should be the request-host of the origin transaction, as defined by **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html]. It defaults to `http.cookiejar.request_host(self)`. This is the host name or IP address of the original request that was initiated

by the user. For example, if the request is for an image in an HTML document, this should be the request-host of the request for the page containing the image.

unverifiable should indicate whether the request is unverifiable, as defined by **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html]. It defaults to `False`. An unverifiable request is one whose URL the user did not have the option to approve. For example, if the request is for an image in an HTML document, and the user had no option to approve the automatic fetching of the image, this should be true.

method should be a string that indicates the HTTP request method that will be used (e.g. `'HEAD'`). If provided, its value is stored in the **`method`** attribute and is used by **`get_method()`**. The default is `'GET'` if *data* is `None` or `'POST'` otherwise. Subclasses may indicate a different default method by setting the **`method`** attribute in the class itself.

Note

The request will not work as expected if the data object is unable to deliver its content more than once (e.g. a file or an iterable that can produce the content only once) and the request is retried for HTTP redirects or authentication. The *data* is sent to the HTTP server right away after the headers. There is no support for a 100-continue expectation in the library.

Changed in version 3.3: **`Request.method`** argument is added to the Request class.

Changed in version 3.4: Default **`Request.method`** may be indicated at the class level.

Changed in version 3.6: Do not raise an error if the `Content-Length` has not been provided and *data* is neither `None` nor a bytes object. Fall back to use chunked transfer encoding instead.

class urllib.request.OpenerDirector

The **OpenerDirector** class opens URLs via **BaseHandler**s chained together. It manages the chaining of handlers, and recovery from errors.

class urllib.request.BaseHandler

This is the base class for all registered handlers — and handles only the simple mechanics of registration.

class urllib.request.HTTPDefaultErrorHandler

A class which defines a default handler for HTTP error responses; all responses are turned into **HTTPError** exceptions.

class urllib.request.HTTPRedirectHandler

A class to handle redirections.

class urllib.request.HTTPCookieProcessor(*cookiejar=None*)

A class to handle HTTP Cookies.

class urllib.request.ProxyHandler(*proxies=None*)

Cause requests to go through a proxy. If *proxies* is given, it must be a dictionary mapping protocol names to URLs of proxies. The default is to read the list of proxies from the environment variables `<protocol>_proxy`. If no proxy environment variables are set, then in a Windows environment proxy settings are obtained from the registry's Internet Settings section, and in a macOS environment proxy information is retrieved from the System Configuration Framework.

To disable autodetected proxy pass an empty dictionary.

The **no_proxy** environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with `:port` appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`.

Note

`HTTP_PROXY` will be ignored if a variable `REQUEST_METHOD` is set; see the documentation on **`getproxies()`**.

class urllib.request.HTTPPasswordMgr

Keep a database of `(realm, uri) -> (user, password)` mappings.

class urllib.request.HTTPPasswordMgrWithDefaultRealm

Keep a database of `(realm, uri) -> (user, password)` mappings. A realm of `None` is considered a catch-all realm, which is searched if no other realm fits.

class urllib.request.HTTPPasswordMgrWithPriorAuth

A variant of **`HTTPPasswordMgrWithDefaultRealm`** that also has a database of `uri -> is_authenticated` mappings. Can be used by a BasicAuth handler to determine when to send authentication credentials immediately instead of waiting for a `401` response first.

New in version 3.5.

class urllib.request.AbstractBasicAuthHandler(*password_mgr=None*)

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password_mgr*, if given, should be something that is compatible with **`HTTPPasswordMgr`**; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported. If *passwd_mgr* also provides `is_authenticated` and `update_authenticated` methods (see HTTPPasswordMgrWithPriorAuth Objects), then the handler will use the `is_authenticated` result for a given URI to determine whether or not to send authentication credentials with the request. If `is_authenticated` returns `True` for

the URI, credentials are sent. If `is_authenticated` is `False`, credentials are not sent, and then if a `401` response is received the request is re-sent with the authentication credentials. If authentication succeeds, `update_authenticated` is called to set `is_authenticated True` for the URI, so that subsequent requests to the URI or any of its super-URIs will automatically include the authentication credentials.

New in version 3.5: Added `is_authenticated` support.

class urllib.request.HTTPBasicAuthHandler(*password_mgr=None*)

Handle authentication with the remote host. *password_mgr*, if given, should be something that is compatible with **`HTTPPasswordMgr`**; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported. HTTPBasicAuthHandler will raise a **`ValueError`** when presented with a wrong Authentication scheme.

class urllib.request.ProxyBasicAuthHandler(*password_mgr=None*)

Handle authentication with the proxy. *password_mgr*, if given, should be something that is compatible with **`HTTPPasswordMgr`**; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class
urllib.request.AbstractDigestAuthHandler(*password_mgr=None*)

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password_mgr*, if given, should be something that is compatible with **`HTTPPasswordMgr`**; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib.request.HTTPDigestAuthHandler(*password_mgr=None*)

Handle authentication with the remote host. *password_mgr*, if given, should be something that is compatible with

HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported. When both Digest Authentication Handler and Basic Authentication Handler are both added, Digest Authentication is always tried first. If the Digest Authentication returns a 40x response again, it is sent to Basic Authentication handler to Handle. This Handler method will raise a **ValueError** when presented with an authentication scheme other than Digest or Basic.

Changed in version 3.3: Raise **ValueError** on unsupported Authentication Scheme.

class urllib.request.ProxyDigestAuthHandler(*password_mgr=None*)

Handle authentication with the proxy. *password_mgr*, if given, should be something that is compatible with **HTTPPasswordMgr**; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib.request.HTTPHandler

A class to handle opening of HTTP URLs.

class urllib.request.HTTPSHandler(*debuglevel=0*, *context=None*, *check_hostname=None*)

A class to handle opening of HTTPS URLs. *context* and *check_hostname* have the same meaning as in **http.client.HTTPSConnection**.

Changed in version 3.2: context and *check_hostname* were added.

class urllib.request.FileHandler

Open local files.

class urllib.request.DataHandler

Open data URLs.

New in version 3.4.

class urllib.request.FTPHandler
: Open FTP URLs.

class urllib.request.CacheFTPHandler
: Open FTP URLs, keeping a cache of open FTP connections to minimize delays.

class urllib.request.UnknownHandler
: A catch-all class to handle unknown URLs.

class urllib.request.HTTPErrorProcessor
: Process HTTP error responses.

Request Objects

The following methods describe `Request`'s public interface, and so all may be overridden in subclasses. It also defines several public attributes that can be used by clients to inspect the parsed request.

Request.full_url
: The original URL passed to the constructor.

  Changed in version 3.4.

  Request.full_url is a property with setter, getter and a deleter. Getting `full_url` returns the original request URL with the fragment, if it was present.

Request.type
: The URI scheme.

Request.host
: The URI authority, typically a host, but may also contain a port separated by a colon.

Request.origin_req_host

The original host for the request, without port.

Request.selector

The URI path. If the **Request** uses a proxy, then selector will be the full URL that is passed to the proxy.

Request.data

The entity body for the request, or `None` if not specified.

Changed in version 3.4: Changing value of **Request.data** now deletes "Content-Length" header if it was previously set or calculated.

Request.unverifiable

boolean, indicates whether the request is unverifiable as defined by **RFC 2965** [https://datatracker.ietf.org/doc/html/rfc2965.html].

Request.method

The HTTP request method to use. By default its value is **None**, which means that **get_method()** will do its normal computation of the method to be used. Its value can be set (thus overriding the default computation in **get_method()**) either by providing a default value by setting it at the class level in a **Request** subclass, or by passing a value in to the **Request** constructor via the *method* argument.

New in version 3.3.

Changed in version 3.4: A default value can now be set in subclasses; previously it could only be set via the constructor argument.

Request.get_method()

Return a string indicating the HTTP request method. If **Request.method** is not `None`, return its value, otherwise return `'GET'` if **Request.data** is `None`, or `'POST'` if it's

not. This is only meaningful for HTTP requests.

Changed in version 3.3: get_method now looks at the value of `Request.method`.

Request.add_header(*key*, *val*)

Add another header to the request. Headers are currently ignored by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the *key* collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header. Note that headers added using this method are also added to redirected requests.

Request.add_unredirected_header(*key*, *header*)

Add a header that will not be added to a redirected request.

Request.has_header(*header*)

Return whether the instance has the named header (checks both regular and unredirected).

Request.remove_header(*header*)

Remove named header from the request instance (both from regular and unredirected headers).

New in version 3.4.

Request.get_full_url()

Return the URL given in the constructor.

Changed in version 3.4.

Returns `Request.full_url`

Request.set_proxy(*host*, *type*)

Prepare the request by connecting to a proxy server. The *host* and *type* will replace those of the instance, and the instance's selector will be the original URL given in the constructor.

Request.get_header(*header_name*, *default*=*None*)

Return the value of the given header. If the header is not present, return the default value.

Request.header_items()

Return a list of tuples (header_name, header_value) of the Request headers.

Changed in version 3.4: The request methods add_data, has_data, get_data, get_type, get_host, get_selector, get_origin_req_host and is_unverifiable that were deprecated since 3.3 have been removed.

OpenerDirector Objects

`OpenerDirector` instances have the following methods:

OpenerDirector.add_handler(*handler*)

handler should be an instance of `BaseHandler`. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case). Note that, in the following, *protocol* should be replaced with the actual protocol to handle, for example `http_response()` would be the HTTP protocol response handler. Also *type* should be replaced with the actual HTTP code, for example `http_error_404()` would handle HTTP 404 errors.

- `<protocol>_open()` — signal that the handler knows how to open *protocol* URLs.

  See `BaseHandler.<protocol>_open()` for more information.

- `http_error_<type>()` — signal that the handler

knows how to handle HTTP errors with HTTP error code *type*.

See **BaseHandler.http_error_<nnn>()** for more information.

- **<protocol>_error()** — signal that the handler knows how to handle errors from (non-`http`) *protocol*.
- **<protocol>_request()** — signal that the handler knows how to pre-process *protocol* requests.

  See **BaseHandler.<protocol>_request()** for more information.

- **<protocol>_response()** — signal that the handler knows how to post-process *protocol* responses.

  See **BaseHandler.<protocol>_response()** for more information.

OpenerDirector.open(*url*, *data*=*None*[, *timeout*])

Open the given *url* (which can be a request object or a string), optionally passing the given *data*. Arguments, return values and exceptions raised are the same as those of **urlopen()** (which simply calls the **open()** method on the currently installed global **OpenerDirector**). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS and FTP connections.

OpenerDirector.error(*proto*, **args*)

Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the **http_error_<type>()** methods of the handler classes.

Return values and exceptions raised are the same as those of **urlopen()**.

OpenerDirector objects open URLs in three stages:

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like **<protocol>_request()** has that method called to pre-process the request.

2. Handlers with a method named like **<protocol>_open()** are called to handle the request. This stage ends when a handler either returns a non-**None** value (ie. a response), or raises an exception (usually **URLError**). Exceptions are allowed to propagate.

   In fact, the above algorithm is first tried for methods named **default_open()**. If all such methods return **None**, the algorithm is repeated for methods named like **<protocol>_open()**. If all such methods return **None**, the algorithm is repeated for methods named **unknown_open()**.

   Note that the implementation of these methods may involve calls of the parent **OpenerDirector** instance's **open()** and **error()** methods.

3. Every handler with a method named like **<protocol>_response()** has that method called to post-process the response.

BaseHandler Objects

BaseHandler objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

BaseHandler.add_parent(*director*)

Add a director as parent.

BaseHandler.close()

Remove any parents.

The following attribute and methods should only be used by classes derived from **BaseHandler**.

Note

The convention has been adopted that subclasses defining **<protocol>_request()** or **<protocol>_response()** methods are named ***Processor**; all others are named ***Handler**.

BaseHandler.parent

A valid **OpenerDirector**, which can be used to open using a different protocol, or handle errors.

BaseHandler.default_open(*req*)

This method is *not* defined in **BaseHandler**, but subclasses should define it if they want to catch all URLs.

This method, if implemented, will be called by the parent **OpenerDirector**. It should return a file-like object as described in the return value of the **open()** method of **OpenerDirector**, or `None`. It should raise **URLError**, unless a truly exceptional thing happens (for example, **MemoryError** should not be mapped to **URLError**).

This method will be called before any protocol-specific open method.

BaseHandler.<protocol>_open(req)

This method is *not* defined in **BaseHandler**, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent **OpenerDirector**. Return values should be the same as for

default_open().

BaseHandler.unknown_open(*req*)

This method is *not* defined in **BaseHandler**, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the **parent OpenerDirector**. Return values should be the same as for **default_open()**.

BaseHandler.http_error_default(*req*, *fp*, *code*, *msg*, *hdrs*)

This method is *not* defined in **BaseHandler**, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the **OpenerDirector** getting the error, and should not normally be called in other circumstances.

req will be a **Request** object, *fp* will be a file-like object with the HTTP error body, *code* will be the three-digit code of the error, *msg* will be the user-visible explanation of the code and *hdrs* will be a mapping object with the headers of the error.

Return values and exceptions raised should be the same as those of **urlopen()**.

BaseHandler.http_error_<nnn>(req, fp, code, msg, hdrs)

nnn should be a three-digit HTTP error code. This method is also not defined in **BaseHandler**, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code *nnn* occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for **http_error_default()**.

BaseHandler.<protocol>_request(req)

This method is *not* defined in **BaseHandler**, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent **OpenerDirector**. *req* will be a **Request** object. The return value should be a **Request** object.

BaseHandler.<protocol>_response(req, response)

This method is *not* defined in **BaseHandler**, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent **OpenerDirector**. *req* will be a **Request** object. *response* will be an object implementing the same interface as the return value of **urlopen()**. The return value should implement the same interface as the return value of **urlopen()**.

HTTPRedirectHandler Objects

Note

Some HTTP redirections require action from this module's client code. If this is the case, **HTTPError** is raised. See **RFC 2616** [https://datatracker.ietf.org/doc/html/rfc2616.html] for details of the precise meanings of the various redirection codes.

An **HTTPError** exception raised as a security consideration if the HTTPRedirectHandler is presented with a redirected URL which is not an HTTP, HTTPS or FTP URL.

HTTPRedirectHandler.redirect_request(*req*, *fp*, *code*, *msg*, *hdrs*, *newurl*)

Return a **Request** or `None` in response to a redirect. This is called by the default implementations of the

http_error_30*() methods when a redirection is received from the server. If a redirection should take place, return a new **Request** to allow **http_error_30*()** to perform the redirect to *newurl*. Otherwise, raise **HTTPError** if no other handler should try to handle this URL, or return `None` if you can't but another handler might.

Note

The default implementation of this method does not strictly follow **RFC 2616** [https://datatracker.ietf.org/doc/html/rfc2616.html], which says that 301 and 302 responses to `POST` requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a `GET`, and the default implementation reproduces this behavior.

HTTPRedirectHandler.http_error_301(*req*, *fp*, *code*, *msg*, *hdrs*)

Redirect to the `Location:` or `URI:` URL. This method is called by the parent **OpenerDirector** when getting an HTTP 'moved permanently' response.

HTTPRedirectHandler.http_error_302(*req*, *fp*, *code*, *msg*, *hdrs*)

The same as **http_error_301()**, but called for the 'found' response.

HTTPRedirectHandler.http_error_303(*req*, *fp*, *code*, *msg*, *hdrs*)

The same as **http_error_301()**, but called for the 'see other' response.

HTTPRedirectHandler.http_error_307(*req*, *fp*, *code*, *msg*, *hdrs*)

The same as **http_error_301()**, but called for the 'temporary redirect' response. It does not allow changing the request method from `POST` to `GET`.

HTTPRedirectHandler.http_error_308(*req*, *fp*, *code*, *msg*, *hdrs*)

The same as **http_error_301()**, but called for the 'permanent redirect' response. It does not allow changing the request method from `POST` to `GET`.

New in version 3.11.

HTTPCookieProcessor Objects

HTTPCookieProcessor instances have one attribute:

HTTPCookieProcessor.cookiejar

The **http.cookiejar.CookieJar** in which cookies are stored.

ProxyHandler Objects

ProxyHandler.<protocol>_open(request)

The **ProxyHandler** will have a method **<protocol>_open()** for every *protocol* which has a proxy in the *proxies* dictionary given in the constructor. The method will modify requests to go through the proxy, by calling `request.set_proxy()`, and call the next handler in the chain to actually execute the protocol.

HTTPPasswordMgr Objects

These methods are available on **HTTPPasswordMgr** and **HTTPPasswordMgrWithDefaultRealm** objects.

HTTPPasswordMgr.add_password(*realm*, *uri*, *user*, *passwd*)

uri can be either a single URI, or a sequence of URIs. *realm*, *user* and *passwd* must be strings. This causes `(user, passwd)` to be used as authentication tokens when authentication for *realm* and a super-URI of any of the given URIs is given.

HTTPPasswordMgr.find_user_password(*realm*, *authuri*)

Get user/password for given realm and URI, if any. This method will return `(None, None)` if there is no matching user/password.

For **`HTTPPasswordMgrWithDefaultRealm`** objects, the realm `None` will be searched if the given *realm* has no matching user/password.

HTTPPasswordMgrWithPriorAuth Objects

This password manager extends **`HTTPPasswordMgrWithDefaultRealm`** to support tracking URIs for which authentication credentials should always be sent.

HTTPPasswordMgrWithPriorAuth.add_password(*realm*, *uri*, *user*, *passwd*, *is_authenticated* = *False*)

realm, *uri*, *user*, *passwd* are as for **`HTTPPasswordMgr.add_password()`**. *is_authenticated* sets the initial value of the `is_authenticated` flag for the given URI or list of URIs. If *is_authenticated* is specified as `True`, *realm* is ignored.

HTTPPasswordMgrWithPriorAuth.find_user_password(*realm*, *authuri*)

Same as for **`HTTPPasswordMgrWithDefaultRealm`** objects

HTTPPasswordMgrWithPriorAuth.update_authenticated(*self*, *uri*, *is_authenticated* = *False*)

Update the `is_authenticated` flag for the given *uri* or list of URIs.

HTTPPasswordMgrWithPriorAuth.is_authenticated(*self*, *authuri*)

Returns the current state of the `is_authenticated` flag for the given URI.

AbstractBasicAuthHandler Objects

AbstractBasicAuthHandler.http_error_auth_reqed(*authreq*, *host*, *req*, *headers*)

Handle an authentication request by getting a user/password pair, and re-trying the request. *authreq* should be the name of the header where the information about the realm is included in the request, *host* specifies the URL and path to authenticate for, *req* should be the (failed) **`Request`** object, and *headers* should be the error headers.

host is either an authority (e.g. `"python.org"`) or a URL containing an authority component (e.g. `"http://python.org/"`). In either case, the authority must not contain a userinfo component (so, `"python.org"` and `"python.org:80"` are fine, `"joe:password@python.org"` is not).

HTTPBasicAuthHandler Objects

HTTPBasicAuthHandler.http_error_401(*req*, *fp*, *code*, *msg*, *hdrs*)

Retry the request with authentication information, if available.

ProxyBasicAuthHandler Objects

ProxyBasicAuthHandler.http_error_407(*req*, *fp*, *code*, *msg*, *hdrs*)

Retry the request with authentication information, if available.

AbstractDigestAuthHandler Objects

AbstractDigestAuthHandler.http_error_auth_reqed(*authreq*, *host*, *req*, *headers*)

authreq should be the name of the header where the

information about the realm is included in the request, *host* should be the host to authenticate to, *req* should be the (failed) `Request` object, and *headers* should be the error headers.

HTTPDigestAuthHandler Objects

HTTPDigestAuthHandler.http_error_401(*req*, *fp*, *code*, *msg*, *hdrs*)

Retry the request with authentication information, if available.

ProxyDigestAuthHandler Objects

ProxyDigestAuthHandler.http_error_407(*req*, *fp*, *code*, *msg*, *hdrs*)

Retry the request with authentication information, if available.

HTTPHandler Objects

HTTPHandler.http_open(*req*)

Send an HTTP request, which can be either GET or POST, depending on `req.has_data()`.

HTTPSHandler Objects

HTTPSHandler.https_open(*req*)

Send an HTTPS request, which can be either GET or POST, depending on `req.has_data()`.

FileHandler Objects

FileHandler.file_open(*req*)

Open the file locally, if there is no host name, or the host name is `'localhost'`.

Changed in version 3.2: This method is applicable only for local hostnames. When a remote hostname is given, an **URLError** is raised.

DataHandler Objects

DataHandler.data_open(*req*)

Read a data URL. This kind of URL contains the content encoded in the URL itself. The data URL syntax is specified in **RFC 2397** [https://datatracker.ietf.org/doc/html/rfc2397.html]. This implementation ignores white spaces in base64 encoded data URLs so the URL may be wrapped in whatever source file it comes from. But even though some browsers don't mind about a missing padding at the end of a base64 encoded data URL, this implementation will raise an **ValueError** in that case.

FTPHandler Objects

FTPHandler.ftp_open(*req*)

Open the FTP file indicated by *req*. The login is always done with empty username and password.

CacheFTPHandler Objects

CacheFTPHandler objects are **FTPHandler** objects with the following additional methods:

CacheFTPHandler.setTimeout(*t*)

Set timeout of connections to *t* seconds.

CacheFTPHandler.setMaxConns(*m*)

Set maximum number of cached connections to *m*.

UnknownHandler Objects

UnknownHandler.unknown_open()

Raise a **URLError** exception.

HTTPErrorProcessor Objects

HTTPErrorProcessor.http_response(*request*, *response*)

Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the **http_error_<type>()** handler methods, via **OpenerDirector.error()**. Eventually, **HTTPDefaultErrorHandler** will raise an **HTTPError** if no other handler handles the error.

HTTPErrorProcessor.https_response(*request*, *response*)

Process HTTPS error responses.

The behavior is same as **http_response()**.

Examples

In addition to the examples below, more examples are given in HOWTO Fetch Internet Resources Using The urllib Package.

This example gets the python.org main page and displays the first 300 bytes of it.

```
>>> import urllib.request
>>> with urllib.request.urlopen('http://www.python.org/'
...     print(f.read(300))
...
b'<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitic
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtc
xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang=
<meta http-equiv="content-type" content="text/html; char
```

```
<title>Python Programming '
```

Note that urlopen returns a bytes object. This is because there is no way for urlopen to automatically determine the encoding of the byte stream it receives from the HTTP server. In general, a program will decode the returned bytes object to string once it determines or guesses the appropriate encoding.

The following W3C document, https://www.w3.org/International/O-charset, lists the various ways in which an (X)HTML or an XML document could have specified its encoding information.

As the python.org website uses *utf-8* encoding as specified in its meta tag, we will use the same for decoding the bytes object.

```
>>> with urllib.request.urlopen('http://www.python.org/'
...     print(f.read(100).decode('utf-8'))
...
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitiona
"http://www.w3.org/TR/xhtml1/DTD/xhtm
```

It is also possible to achieve the same result without using the context manager approach.

```
>>> import urllib.request
>>> f = urllib.request.urlopen('http://www.python.org/')
>>> print(f.read(100).decode('utf-8'))
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitiona
"http://www.w3.org/TR/xhtml1/DTD/xhtm
```

In the following example, we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```
>>> import urllib.request
>>> req = urllib.request.Request(url='https://localhost/
...                       data=b'This data is passed to
>>> with urllib.request.urlopen(req) as f:
...     print(f.read().decode('utf-8'))
...
Got Data: "This data is passed to stdin of the CGI"
```

The code for the sample CGI used in the above example is:

```
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print('Content-type: text/plain\n\nGot Data: "%s"' % dat
```

Here is an example of doing a `PUT` request using **`Request`**:

```
import urllib.request
DATA = b'some data'
req = urllib.request.Request(url='http://localhost:8080'
with urllib.request.urlopen(req) as f:
    pass
print(f.status)
print(f.reason)
```

Use of Basic HTTP Authentication:

```
import urllib.request
# Create an OpenerDirector with support for Basic HTTP A
auth_handler = urllib.request.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
                          uri='https://mahler:8092/site-
                          user='klem',
                          passwd='kadidd!ehopper')
opener = urllib.request.build_opener(auth_handler)
# ...and install it globally so it can be used with urlo
urllib.request.install_opener(opener)
urllib.request.urlopen('http://www.example.com/login.htm
```

`build_opener()` provides many handlers by default, including a **`ProxyHandler`**. By default, **`ProxyHandler`** uses the environment variables named `<scheme>_proxy`, where `<scheme>` is the URL scheme involved. For example, the **`http_proxy`** environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default **`ProxyHandler`** with one that uses programmatically supplied proxy URLs, and adds proxy authorization support with **`ProxyBasicAuthHandler`**.

```
proxy_handler = urllib.request.ProxyHandler({'http': 'ht
proxy_auth_handler = urllib.request.ProxyBasicAuthHandle
proxy_auth_handler.add_password('realm', 'host', 'userna

opener = urllib.request.build_opener(proxy_handler, prox
# This time, rather than install the OpenerDirector, we
opener.open('http://www.example.com/login.html')
```

Adding HTTP headers:

Use the *headers* argument to the **`Request`** constructor, or:

```
import urllib.request
req = urllib.request.Request('http://www.example.com/')
req.add_header('Referer', 'http://www.python.org/')
# Customize the default User-Agent header value:
req.add_header('User-Agent', 'urllib-example/0.1 (Contac
r = urllib.request.urlopen(req)
```

`OpenerDirector` automatically adds a *User-Agent* header to every **`Request`**. To change this:

```
import urllib.request
opener = urllib.request.build_opener()
opener.addheaders = [('User-agent', 'Mozilla/5.0')]
opener.open('http://www.example.com/')
```

Also, remember that a few standard headers (*Content-Length*, *Content-Type* and *Host*) are added when the **`Request`** is passed to **`urlopen()`** (or **`OpenerDirector.open()`**).

Here is an example session that uses the `GET` method to retrieve a URL containing parameters:

```
>>> import urllib.request
>>> import urllib.parse
>>> params = urllib.parse.urlencode({'spam': 1, 'eggs':
>>> url = "http://www.musi-cal.com/cgi-bin/query?%s" % p
>>> with urllib.request.urlopen(url) as f:
...     print(f.read().decode('utf-8'))
```

```
...
```

The following example uses the `POST` method instead. Note that params output from urlencode is encoded to bytes before it is sent to urlopen as data:

```
>>> import urllib.request
>>> import urllib.parse
>>> data = urllib.parse.urlencode({'spam': 1, 'eggs': 2,
>>> data = data.encode('ascii')
>>> with urllib.request.urlopen("http://requestb.in/xrbl
...     print(f.read().decode('utf-8'))
...
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```
>>> import urllib.request
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.request.FancyURLopener(proxies)
>>> with opener.open("http://www.python.org") as f:
...     f.read().decode('utf-8')
...
```

The following example uses no proxies at all, overriding environment settings:

```
>>> import urllib.request
>>> opener = urllib.request.FancyURLopener({})
>>> with opener.open("http://www.python.org/") as f:
...     f.read().decode('utf-8')
...
```

Legacy interface

The following functions and classes are ported from the Python 2 module `urllib` (as opposed to `urllib2`). They might become deprecated at some point in the future.

urllib.request.urlretrieve(*url*, *filename*=*None*, *reporthook*=*None*,

data=*None*)

Copy a network object denoted by a URL to a local file. If the URL points to a local file, the object will not be copied unless filename is supplied. Return a tuple `(filename, headers)` where *filename* is the local file name under which the object can be found, and *headers* is whatever the **`info()`** method of the object returned by **`urlopen()`** returned (for a remote object). Exceptions are the same as for **`urlopen()`**.

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a callable that will be called once on establishment of the network connection and once after each block read thereafter. The callable will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be `-1` on older FTP servers which do not return a file size in response to a retrieval request.

The following example illustrates the most common usage scenario:

```
>>> import urllib.request
>>> local_filename, headers = urllib.request.urlret
>>> html = open(local_filename)
>>> html.close()
```

If the *url* uses the `http:` scheme identifier, the optional *data* argument may be given to specify a `POST` request (normally the request type is `GET`). The *data* argument must be a bytes object in standard *application/x-www-form-urlencoded* format; see the **`urllib.parse.urlencode()`** function.

`urlretrieve()` will raise **`ContentTooShortError`** when it detects that the amount of data available was less than the expected amount (which is the size reported by a *Content-Length* header). This can occur, for example, when the download is interrupted.

The *Content-Length* is treated as a lower bound: if there's more data to read, urlretrieve reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the **`content`** attribute of the exception instance.

If no *Content-Length* header was supplied, urlretrieve can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

urllib.request.urlcleanup()

Cleans up temporary files that may have been left behind by previous calls to **`urlretrieve()`**.

class urllib.request.URLopener(*proxies=None*, ***x509*)

Deprecated since version 3.3.

Base class for opening and reading URLs. Unless you need to support opening objects using schemes other than `http:`, `ftp:`, or `file:`, you probably want to use **`FancyURLopener`**.

By default, the **`URLopener`** class sends a *User-Agent* header of `urllib/VVV`, where *VVV* is the **`urllib`** version number. Applications can define their own *User-Agent* header by subclassing **`URLopener`** or **`FancyURLopener`** and setting the class attribute **`version`** to an appropriate string value in the subclass definition.

The optional *proxies* parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is `None`, in which case environmental proxy settings will be used if present, as discussed in the definition of **`urlopen()`**, above.

Additional keyword parameters, collected in *x509*, may be used for authentication of the client when using the `https:`

scheme. The keywords *key_file* and *cert_file* are supported to provide an SSL key and certificate; both are needed to support client authentication.

URLopener objects will raise an **OSError** exception if the server returns an error code.

open(*fullurl*, *data*=*None*)

Open *fullurl* using the appropriate protocol. This method sets up cache and proxy information, then calls the appropriate open method with its input arguments. If the scheme is not recognized, **open_unknown()** is called. The *data* argument has the same meaning as the *data* argument of **urlopen()**.

This method always quotes *fullurl* using **quote()**.

open_unknown(*fullurl*, *data*=*None*)

Overridable interface to open unknown URL types.

retrieve(*url*, *filename*=*None*, *reporthook*=*None*, *data*=*None*)

Retrieves the contents of *url* and places it in *filename*. The return value is a tuple consisting of a local filename and either an **email.message.Message** object containing the response headers (for remote URLs) or `None` (for local URLs). The caller must then open and read the contents of *filename*. If *filename* is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and *filename* is not given, the filename is the output of **tempfile.mktemp()** with a suffix that matches the suffix of the last path component of the input URL. If *reporthook* is given, it must be a function accepting three numeric parameters: A chunk number, the maximum size chunks are read in and the total size of the download (-1 if unknown). It will be called once at the start and after each chunk of data is read from the network. *reporthook* is ignored for local URLs.

If the *url* uses the `http:` scheme identifier, the optional *data* argument may be given to specify a `POST` request (normally the request type is `GET`). The *data* argument must in standard *application/x-www-form-urlencoded* format; see the **`urllib.parse.urlencode()`** function.

version

Variable that specifies the user agent of the opener object. To get **`urllib`** to tell servers that it is a particular user agent, set this in a subclass as a class variable or in the constructor before calling the base constructor.

class urllib.request.FancyURLopener(...)

Deprecated since version 3.3.

`FancyURLopener` subclasses **`URLopener`** providing default handling for the following HTTP response codes: 301, 302, 303, 307 and 401. For the 30x response codes listed above, the *Location* header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the *maxtries* attribute, which defaults to 10.

For all other response codes, the method **`http_error_default()`** is called which you can override in subclasses to handle the error appropriately.

Note

According to the letter of **RFC 2616** [https://datatracker.ietf.org/doc/html/rfc2616.html], 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and **`urllib`** reproduces this behaviour.

The parameters to the constructor are the same as those for `URLopener`.

Note

When performing basic authentication, a `FancyURLopener` instance calls its `prompt_user_passwd()` method. The default implementation asks the users for the required information on the controlling terminal. A subclass may override this method to support more appropriate behavior if needed.

The `FancyURLopener` class offers one additional method that should be overloaded to provide the appropriate behavior:

prompt_user_passwd(*host*, *realm*)

Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, `(user, password)`, which can be used for basic authentication.

The implementation prompts for this information on the terminal; an application should override this method to use an appropriate interaction model in the local environment.

`urllib.request` Restrictions

- Currently, only the following protocols are supported: HTTP (versions 0.9 and 1.0), FTP, local files, and data URLs.

  Changed in version 3.4: Added support for data URLs.

- The caching feature of `urlretrieve()` has been disabled until someone finds the time to hack proper processing of Expiration time headers.

- There should be a function to query whether a particular URL

is in the cache.

- For backward compatibility, if a URL appears to point to a local file but the file can't be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.

- The **`urlopen()`** and **`urlretrieve()`** functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive web client using these functions without using threads.

- The data returned by **`urlopen()`** or **`urlretrieve()`** is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the *Content-Type* header. If the returned data is HTML, you can use the module **`html.parser`** to parse it.

- The code handling the FTP protocol cannot differentiate between a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL ends in a `/`, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing `/` has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the **`ftplib`** module, subclassing **`FancyURLopener`**, or changing *_urlopener* to meet your needs.

`urllib.response` — Response classes used by urllib

The `urllib.response` module defines functions and classes which define a minimal file-like interface, including `read()` and `readline()`. Functions defined by this module are used internally by the `urllib.request` module. The typical response object is a `urllib.response.addinfourl` instance:

class urllib.response.addinfourl

url

URL of the resource retrieved, commonly used to determine if a redirect was followed.

headers

Returns the headers of the response in the form of an `EmailMessage` instance.

status

New in version 3.9.

Status code returned by server.

geturl()

Deprecated since version 3.9: Deprecated in favor of `url`.

info()

Deprecated since version 3.9: Deprecated in favor of `headers`.

code

Deprecated since version 3.9: Deprecated in favor of `status`.

getstatus()

Deprecated since version 3.9: Deprecated in favor of **`status`**.

`urllib.parse` — Parse URLs into components

Source code: Lib/urllib/parse.py [https://github.com/python/cpython/tree/3.11/Lib/urllib/parse.py]

This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a "relative URL" to an absolute URL given a "base URL."

The module has been designed to match the internet RFC on Relative Uniform Resource Locators. It supports the following URL schemes: `file`, `ftp`, `gopher`, `hdl`, `http`, `https`, `imap`, `mailto`, `mms`, `news`, `nntp`, `prospero`, `rsync`, `rtsp`, `rtspu`, `sftp`, `shttp`, `sip`, `sips`, `snews`, `svn`, `svn+ssh`, `telnet`, `wais`, `ws`, `wss`.

The `urllib.parse` module defines functions that fall into two broad categories: URL parsing and URL quoting. These are covered in detail in the following sections.

URL Parsing

The URL parsing functions focus on splitting a URL string into its components, or on combining URL components into a URL string.

urllib.parse.urlparse(*urlstring*, *scheme*='', *allow_fragments*=*True*)

Parse a URL into six components, returning a 6-item named tuple. This corresponds to the general structure of a URL: `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken up into smaller parts

(for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the *path* component, which is retained if present. For example:

```
>>> from urllib.parse import urlparse
>>> urlparse("scheme://netloc/path;parameters?query
ParseResult(scheme='scheme', netloc='netloc', path=
            query='query', fragment='fragment')
>>> o = urlparse("http://docs.python.org:80/3/libra
...              "highlight=params#url-parsing")
>>> o
ParseResult(scheme='http', netloc='docs.python.org:
            path='/3/library/urllib.parse.html', pa
            query='highlight=params', fragment='url
>>> o.scheme
'http'
>>> o.netloc
'docs.python.org:80'
>>> o.hostname
'docs.python.org'
>>> o.port
80
>>> o._replace(fragment="").geturl()
'http://docs.python.org:80/3/library/urllib.parse.h
```

Following the syntax specifications in **RFC 1808** [https://datatracker.ietf.org/doc/html/rfc1808.html], urlparse recognizes a netloc only if it is properly introduced by '//'. Otherwise the input is presumed to be a relative URL and thus to start with a path component.

```
>>> from urllib.parse import urlparse
>>> urlparse('//www.cwi.nl:80/%7Eguido/Python.html'
ParseResult(scheme='', netloc='www.cwi.nl:80', path
            params='', query='', fragment='')
>>> urlparse('www.cwi.nl/%7Eguido/Python.html')
ParseResult(scheme='', netloc='', path='www.cwi.nl/
            params='', query='', fragment='')
```

```
>>> urlparse('help/Python.html')
ParseResult(scheme='', netloc='', path='help/Python
            query='', fragment='')
```

The *scheme* argument gives the default addressing scheme, to be used only if the URL does not specify one. It should be the same type (text or bytes) as *urlstring*, except that the default value `''` is always allowed, and is automatically converted to `b''` if appropriate.

If the *allow_fragments* argument is false, fragment identifiers are not recognized. Instead, they are parsed as part of the path, parameters or query component, and **`fragment`** is set to the empty string in the return value.

The return value is a named tuple, which means that its items can be accessed by index or as named attributes, which are:

Attribute	Index	Value if not present
scheme	0	URL scheme specifier
netloc	1	Network location part
path	2	Hierarchical path
params	3	Parameters for last path element
query	4	Query component
fragment	5	Fragment identifier
username		User name
password		Password
hostname		Host name (lower case)
port		Port number as integer, if present

Reading the **`port`** attribute will raise a **`ValueError`** if an invalid port is specified in the URL. See section Structured Parse Results for more information on the result object.

Unmatched square brackets in the **`netloc`** attribute will raise a **`ValueError`**.

Characters in the **`netloc`** attribute that decompose under NFKC normalization (as used by the IDNA encoding) into any of `/`, `?`, `#`, `@`, or `:` will raise a **`ValueError`**. If the URL is decomposed before parsing, no error will be raised.

As is the case with all named tuples, the subclass has a few additional methods and attributes that are particularly useful. One such method is **_replace()**. The **_replace()** method will return a new ParseResult object replacing specified fields with new values.

```
>>> from urllib.parse import urlparse
>>> u = urlparse('//www.cwi.nl:80/%7Eguido/Python.h
>>> u
ParseResult(scheme='', netloc='www.cwi.nl:80', path
            params='', query='', fragment='')
>>> u._replace(scheme='http')
ParseResult(scheme='http', netloc='www.cwi.nl:80',
            params='', query='', fragment='')
```

Changed in version 3.2: Added IPv6 URL parsing capabilities.

Changed in version 3.3: The fragment is now parsed for all URL schemes (unless *allow_fragment* is false), in accordance with **RFC 3986** [https://datatracker.ietf.org/doc/html/rfc3986.html]. Previously, an allowlist of schemes that support fragments existed.

Changed in version 3.6: Out-of-range port numbers now raise **ValueError**, instead of returning **None**.

Changed in version 3.8: Characters that affect netloc parsing under NFKC normalization will now raise **ValueError**.

urllib.parse.parse_qs(*qs*, *keep_blank_values=False*, *strict_parsing=False*, *encoding='utf-8'*, *errors='replace'*, *max_num_fields=None*, *separator='&'*)

Parse a query string given as a string argument (data of type *application/x-www-form-urlencoded*). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument *keep_blank_values* is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks

should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument *strict_parsing* is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a **ValueError** exception.

The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the **bytes.decode()** method.

The optional argument *max_num_fields* is the maximum number of fields to read. If set, then throws a **ValueError** if there are more than *max_num_fields* fields read.

The optional argument *separator* is the symbol to use for separating the query arguments. It defaults to `&`.

Use the **urllib.parse.urlencode()** function (with the `doseq` parameter set to `True`) to convert such dictionaries into query strings.

Changed in version 3.2: Add *encoding* and *errors* parameters.

Changed in version 3.8: Added *max_num_fields* parameter.

Changed in version 3.10: Added *separator* parameter with the default value of `&`. Python versions earlier than Python 3.10 allowed using both `;` and `&` as query parameter separator. This has been changed to allow only a single separator key, with `&` as the default separator.

urllib.parse.parse_qsl(*qs*, *keep_blank_values=False*, *strict_parsing=False*, *encoding='utf-8'*, *errors='replace'*, *max_num_fields=None*, *separator='&'*)

Parse a query string given as a string argument (data of type *application/x-www-form-urlencoded*). Data are returned as a list of name, value pairs.

The optional argument *keep_blank_values* is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument *strict_parsing* is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a **`ValueError`** exception.

The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the **`bytes.decode()`** method.

The optional argument *max_num_fields* is the maximum number of fields to read. If set, then throws a **`ValueError`** if there are more than *max_num_fields* fields read.

The optional argument *separator* is the symbol to use for separating the query arguments. It defaults to `&`.

Use the **`urllib.parse.urlencode()`** function to convert such lists of pairs into query strings.

Changed in version 3.2: Add *encoding* and *errors* parameters.

Changed in version 3.8: Added *max_num_fields* parameter.

Changed in version 3.10: Added *separator* parameter with the default value of `&`. Python versions earlier than Python 3.10 allowed using both `;` and `&` as query parameter separator. This has been changed to allow only a single separator key, with `&` as the default separator.

urllib.parse.urlunparse(*parts*)

Construct a URL from a tuple as returned by `urlparse()`. The *parts* argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for

example, a `?` with an empty query; the RFC states that these are equivalent).

urllib.parse.urlsplit(*urlstring*, *scheme*='', *allow_fragments*=*True*)

This is similar to **`urlparse()`**, but does not split the params from the URL. This should generally be used instead of **`urlparse()`** if the more recent URL syntax allowing parameters to be applied to each segment of the *path* portion of the URL (see **RFC 2396** [https://datatracker.ietf.org/doc/html/rfc2396.html]) is wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-item named tuple:

```
(addressing scheme, network location, path, query,
```

The return value is a named tuple, its items can be accessed by index or as named attributes:

Attribute	Index	Value if not present
scheme	0	URL scheme specifier
netloc	1	Network location part
path	2	Hierarchical path
query	3	Query component
fragment	4	Fragment identifier
username		User name
password		Password
hostname		Host name (lower case)
port		Port number as integer, if present

Reading the **`port`** attribute will raise a **`ValueError`** if an invalid port is specified in the URL. See section Structured Parse Results for more information on the result object.

Unmatched square brackets in the **`netloc`** attribute will raise a **`ValueError`**.

Characters in the **`netloc`** attribute that decompose under NFKC normalization (as used by the IDNA encoding) into any of `/`, `?`, `#`, `@`, or `:` will raise a **`ValueError`**. If the URL is decomposed before parsing, no error will be raised.

Following the WHATWG spec [https://url.spec.whatwg.org/#concept-basic-url-parser] that updates RFC 3986, ASCII newline `\n`, `\r` and tab `\t` characters are stripped from the URL.

Changed in version 3.6: Out-of-range port numbers now raise **`ValueError`**, instead of returning **`None`**.

Changed in version 3.8: Characters that affect netloc parsing under NFKC normalization will now raise **`ValueError`**.

Changed in version 3.10: ASCII newline and tab characters are stripped from the URL.

urllib.parse.urlunsplit(*parts*)

Combine the elements of a tuple as returned by **`urlsplit()`** into a complete URL as a string. The *parts* argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

urllib.parse.urljoin(*base*, *url*, *allow_fragments* = *True*)

Construct a full ("absolute") URL by combining a "base URL" (*base*) with another URL (*url*). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```
>>> from urllib.parse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The *allow_fragments* argument has the same meaning and default as for **`urlparse()`**.

Note

If *url* is an absolute URL (that is, it starts with `//` or `scheme://`), the *url*'s hostname and/or scheme will be

present in the result. For example:

```
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.htm
...         '//www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```

If you do not want that behavior, preprocess the *url* with **`urlsplit()`** and **`urlunsplit()`**, removing possible *scheme* and *netloc* parts.

Changed in version 3.5: Behavior updated to match the semantics defined in **RFC 3986** [https://datatracker.ietf.org/doc/html/rfc3986.html].

urllib.parse.urldefrag(*url*)

If *url* contains a fragment identifier, return a modified version of *url* with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in *url*, return *url* unmodified and an empty string.

The return value is a named tuple, its items can be accessed by index or as named attributes:

Attribute	Index	Value	Value if not present
url	0	URL with no fragment	empty string
fragment	1	Fragment identifier	empty string

See section Structured Parse Results for more information on the result object.

Changed in version 3.2: Result is a structured object rather than a simple 2-tuple.

urllib.parse.unwrap(*url*)

Extract the url from a wrapped URL (that is, a string formatted as `<URL:scheme://host/path>`, `<scheme://host/path>`, `URL:scheme://host/path` or `scheme://host/path`). If *url* is not a wrapped URL, it is returned without changes.

Parsing ASCII Encoded Bytes

The URL parsing functions were originally designed to operate on character strings only. In practice, it is useful to be able to manipulate properly quoted and encoded URLs as sequences of ASCII bytes. Accordingly, the URL parsing functions in this module all operate on **bytes** and **bytearray** objects in addition to **str** objects.

If **str** data is passed in, the result will also contain only **str** data. If **bytes** or **bytearray** data is passed in, the result will contain only **bytes** data.

Attempting to mix **str** data with **bytes** or **bytearray** in a single function call will result in a **TypeError** being raised, while attempting to pass in non-ASCII byte values will trigger **UnicodeDecodeError**.

To support easier conversion of result objects between **str** and **bytes**, all return values from URL parsing functions provide either an **encode()** method (when the result contains **str** data) or a **decode()** method (when the result contains **bytes** data). The signatures of these methods match those of the corresponding **str** and **bytes** methods (except that the default encoding is `'ascii'` rather than `'utf-8'`). Each produces a value of a corresponding type that contains either **bytes** data (for **encode()** methods) or **str** data (for **decode()** methods).

Applications that need to operate on potentially improperly quoted URLs that may contain non-ASCII data will need to do their own decoding from bytes to characters before invoking the URL parsing methods.

The behaviour described in this section applies only to the URL parsing functions. The URL quoting functions use their own rules when producing or consuming byte sequences as detailed in the documentation of the individual URL quoting functions.

Changed in version 3.2: URL parsing functions now accept ASCII encoded byte sequences

Structured Parse Results

The result objects from the **urlparse()**, **urlsplit()** and **urldefrag()** functions are subclasses of the **tuple** type. These subclasses add the attributes listed in the documentation for those functions, the encoding and decoding support described in the previous section, as well as an additional method:

urllib.parse.SplitResult.geturl()

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme may be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

For **urldefrag()** results, only empty fragment identifiers will be removed. For **urlsplit()** and **urlparse()** results, all noted changes will be made to the URL returned by this method.

The result of this method remains unchanged if passed back through the original parsing function:

```
>>> from urllib.parse import urlsplit
>>> url = 'HTTP://www.Python.org/doc/#'
>>> r1 = urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/'
>>> r2 = urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

The following classes provide the implementations of the structured parse results when operating on **str** objects:

class urllib.parse.DefragResult(*url*, *fragment*)

Concrete class for **urldefrag()** results containing **str** data. The **encode()** method returns a **DefragResultBytes** instance.

New in version 3.2.

class urllib.parse.ParseResult(*scheme*, *netloc*, *path*, *params*, *query*, *fragment*)

Concrete class for **urlparse()** results containing **str** data. The **encode()** method returns a **ParseResultBytes** instance.

class urllib.parse.SplitResult(*scheme*, *netloc*, *path*, *query*, *fragment*)

Concrete class for **urlsplit()** results containing **str** data. The **encode()** method returns a **SplitResultBytes** instance.

The following classes provide the implementations of the parse results when operating on **bytes** or **bytearray** objects:

class urllib.parse.DefragResultBytes(*url*, *fragment*)

Concrete class for **urldefrag()** results containing **bytes** data. The **decode()** method returns a **DefragResult** instance.

New in version 3.2.

class urllib.parse.ParseResultBytes(*scheme*, *netloc*, *path*, *params*, *query*, *fragment*)

Concrete class for **urlparse()** results containing **bytes** data. The **decode()** method returns a **ParseResult** instance.

New in version 3.2.

class urllib.parse.SplitResultBytes(*scheme*, *netloc*, *path*, *query*, *fragment*)

Concrete class for **urlsplit()** results containing **bytes** data. The **decode()** method returns a **SplitResult** instance.

New in version 3.2.

URL Quoting

The URL quoting functions focus on taking program data and making it safe for use as URL components by quoting special characters and appropriately encoding non-ASCII text. They also support reversing these operations to recreate the original data from the contents of a URL component if that task isn't already covered by the URL parsing functions above.

urllib.parse.quote(*string*, *safe*='/', *encoding*=*None*, *errors*=*None*)

Replace special characters in *string* using the `%xx` escape. Letters, digits, and the characters `'_.-~'` are never quoted. By default, this function is intended for quoting the path section of a URL. The optional *safe* parameter specifies additional ASCII characters that should not be quoted — its default value is `'/'`.

string may be either a **`str`** or a **`bytes`** object.

Changed in version 3.7: Moved from **RFC 2396** [https://datatracker.ietf.org/doc/html/rfc2396.html] to **RFC 3986** [https://datatracker.ietf.org/doc/html/rfc3986.html] for quoting URL strings. "~" is now included in the set of unreserved characters.

The optional *encoding* and *errors* parameters specify how to deal with non-ASCII characters, as accepted by the **`str.encode()`** method. *encoding* defaults to `'utf-8'`. *errors* defaults to `'strict'`, meaning unsupported characters raise a **`UnicodeEncodeError`**. *encoding* and *errors* must not be supplied if *string* is a **`bytes`**, or a **`TypeError`** is raised.

Note that `quote(string, safe, encoding, errors)` is equivalent to `quote_from_bytes(string.encode(encoding, errors), safe)`.

Example: `quote('/El Niño/')` yields `'/El%20Ni`

`%C3%B1o/'`.

urllib.parse.quote_plus(*string*, *safe*=*''*, *encoding*=*None*, *errors*=*None*)

Like **`quote()`**, but also replace spaces with plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in *safe*. It also does not have *safe* default to `'/'`.

Example: `quote_plus('/El Niño/')` yields `'%2FEl+Ni%C3%B1o%2F'`.

urllib.parse.quote_from_bytes(*bytes*, *safe*=*'/'*)

Like **`quote()`**, but accepts a **`bytes`** object rather than a **`str`**, and does not perform string-to-bytes encoding.

Example: `quote_from_bytes(b'a&\xef')` yields `'a%26%EF'`.

urllib.parse.unquote(*string*, *encoding*=*'utf-8'*, *errors*=*'replace'*)

Replace `%xx` escapes with their single-character equivalent. The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the **`bytes.decode()`** method.

string may be either a **`str`** or a **`bytes`** object.

encoding defaults to `'utf-8'`. *errors* defaults to `'replace'`, meaning invalid sequences are replaced by a placeholder character.

Example: `unquote('/El%20Ni%C3%B1o/')` yields `'/El Niño/'`.

Changed in version 3.9: string parameter supports bytes and str objects (previously only str).

urllib.parse.unquote_plus(*string*, *encoding*=*'utf-8'*, *errors*=*'replace'*)

Like **`unquote()`**, but also replace plus signs with spaces, as

required for unquoting HTML form values.

string must be a **str**.

Example: `unquote_plus('/El+Ni%C3%B1o/')` yields `'/El Niño/'`.

urllib.parse.unquote_to_bytes(*string*)

Replace `%xx` escapes with their single-octet equivalent, and return a **bytes** object.

string may be either a **str** or a **bytes** object.

If it is a **str**, unescaped non-ASCII characters in *string* are encoded into UTF-8 bytes.

Example: `unquote_to_bytes('a%26%EF')` yields `b'a&\xef'`.

urllib.parse.urlencode(*query*, *doseq*=*False*, *safe*='', *encoding*=*None*, *errors*=*None*, *quote_via*=*quote_plus*)

Convert a mapping object or a sequence of two-element tuples, which may contain **str** or **bytes** objects, to a percent-encoded ASCII text string. If the resultant string is to be used as a *data* for POST operation with the **urlopen()** function, then it should be encoded to bytes, otherwise it would result in a **TypeError**.

The resulting string is a series of `key=value` pairs separated by `'&'` characters, where both *key* and *value* are quoted using the *quote_via* function. By default, **quote_plus()** is used to quote the values, which means spaces are quoted as a `'+'` character and '/' characters are encoded as `%2F`, which follows the standard for GET requests (`application/x-www-form-urlencoded`). An alternate function that can be passed as *quote_via* is **quote()**, which will encode spaces as `%20` and not encode '/' characters. For maximum control of what is quoted, use `quote` and specify a value for *safe*.

When a sequence of two-element tuples is used as the *query*

argument, the first element of each tuple is a key and the second is a value. The value element in itself can be a sequence and in that case, if the optional parameter *doseq* evaluates to `True`, individual `key=value` pairs separated by `'&'` are generated for each element of the value sequence for the key. The order of parameters in the encoded string will match the order of parameter tuples in the sequence.

The *safe*, *encoding*, and *errors* parameters are passed down to *quote_via* (the *encoding* and *errors* parameters are only passed when a query element is a **`str`**).

To reverse this encoding process, **`parse_qs()`** and **`parse_qsl()`** are provided in this module to parse query strings into Python data structures.

Refer to urllib examples to find out how the **`urllib.parse.urlencode()`** method can be used for generating the query string of a URL or data for a POST request.

Changed in version 3.2: query supports bytes and string objects.

New in version 3.5: quote_via parameter.

`urllib.error` — Exception classes raised by urllib.request

Source code: Lib/urllib/error.py [https://github.com/python/cpython/tree/3.11/Lib/urllib/error.py]

The `urllib.error` module defines the exception classes for exceptions raised by `urllib.request`. The base exception class is `URLError`.

The following exceptions are raised by `urllib.error` as appropriate:

exception urllib.error.URLError

The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of `OSError`.

reason

The reason for this error. It can be a message string or another exception instance.

Changed in version 3.3: `URLError` has been made a subclass of `OSError` instead of `IOError`.

exception urllib.error.HTTPError

Though being an exception (a subclass of `URLError`), an `HTTPError` can also function as a non-exceptional file-like return value (the same thing that `urlopen()` returns). This is useful when handling exotic HTTP errors, such as requests for authentication.

code

An HTTP status code as defined in **RFC 2616** [https://datatracker.ietf.org/doc/html/rfc2616.html]. This numeric

value corresponds to a value found in the dictionary of codes as found in **`http.server.BaseHTTPRequestHandler.responses`**.

reason

This is usually a string explaining the reason for this error.

headers

The HTTP response headers for the HTTP request that caused the **`HTTPError`**.

New in version 3.4.

exception urllib.error.ContentTooShortError(*msg*, *content*)

This exception is raised when the **`urlretrieve()`** function detects that the amount of the downloaded data is less than the expected amount (given by the *Content-Length* header). The **`content`** attribute stores the downloaded (and supposedly truncated) data.

`urllib.robotparser` — Parser for robots.txt

Source code: Lib/urllib/robotparser.py [https://github.com/python/cpython/tree/3.11/Lib/urllib/robotparser.py]

This module provides a single class, **`RobotFileParser`**, which answers questions about whether or not a particular user agent can fetch a URL on the web site that published the `robots.txt` file. For more details on the structure of `robots.txt` files, see http://www.robotstxt.org/orig.html.

class urllib.robotparser.RobotFileParser(*url*='')

This class provides methods to read, parse and answer questions about the `robots.txt` file at *url*.

set_url(*url*)

Sets the URL referring to a `robots.txt` file.

read()

Reads the `robots.txt` URL and feeds it to the parser.

parse(*lines*)

Parses the lines argument.

can_fetch(*useragent*, *url*)

Returns `True` if the *useragent* is allowed to fetch the *url* according to the rules contained in the parsed `robots.txt` file.

mtime()

Returns the time the `robots.txt` file was last fetched. This is useful for long-running web spiders that need to check for new `robots.txt` files periodically.

modified()

Sets the time the `robots.txt` file was last fetched to the current time.

crawl_delay(*useragent*)

Returns the value of the `Crawl-delay` parameter from `robots.txt` for the *useragent* in question. If there is no such parameter or it doesn't apply to the *useragent* specified or the `robots.txt` entry for this parameter has invalid syntax, return `None`.

New in version 3.6.

request_rate(*useragent*)

Returns the contents of the `Request-rate` parameter from `robots.txt` as a named tuple `RequestRate(requests, seconds)`. If there is no such parameter or it doesn't apply to the *useragent* specified or the `robots.txt` entry for this parameter has invalid syntax, return `None`.

New in version 3.6.

site_maps()

Returns the contents of the `Sitemap` parameter from `robots.txt` in the form of a **`list()`**. If there is no such parameter or the `robots.txt` entry for this parameter has invalid syntax, return `None`.

New in version 3.8.

The following example demonstrates basic use of the **`RobotFileParser`** class:

```
>>> import urllib.robotparser
>>> rp = urllib.robotparser.RobotFileParser()
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rrate = rp.request_rate("*")
>>> rrate.requests
3
>>> rrate.seconds
20
>>> rp.crawl_delay("*")
6
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/s
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/")
True
```

`http` — HTTP modules

Source code: Lib/http/__init__.py [https://github.com/python/cpython/tree/3.11/Lib/http/__init__.py]

`http` is a package that collects several modules for working with the HyperText Transfer Protocol:

- `http.client` is a low-level HTTP protocol client; for high-level URL opening use `urllib.request`
- `http.server` contains basic HTTP server classes based on `socketserver`
- `http.cookies` has utilities for implementing state management with cookies
- `http.cookiejar` provides persistence of cookies

The `http` module also defines the following enums that help you work with http related code:

class http.HTTPStatus

New in version 3.5.

A subclass of `enum.IntEnum` that defines a set of HTTP status codes, reason phrases and long descriptions written in English.

Usage:

```
>>> from http import HTTPStatus
>>> HTTPStatus.OK
HTTPStatus.OK
>>> HTTPStatus.OK == 200
True
>>> HTTPStatus.OK.value
200
>>> HTTPStatus.OK.phrase
```

```
'OK'
>>> HTTPStatus.OK.description
'Request fulfilled, document follows'
>>> list(HTTPStatus)
[HTTPStatus.CONTINUE, HTTPStatus.SWITCHING_PROTOCOL
```

HTTP status codes

Supported, IANA-registered status codes [https://www.iana.org/assignments/http-status-codes/http-status-codes.xhtml] available in **`http.HTTPStatus`** are:

Code	Name	Details
100	`CONTINUE`	HTTP/1.1 RFC 7231, Section 6.2.1
101	`SWITCHING_PROTOCOLS`	HTTP/1.1 RFC 7231, Section 6.2.2
102	`PROCESSING`	WebDAV RFC 2518, Section 10.1
103	`EARLY_HINTS`	An HTTP Status Code for Indicating Hints RFC 8297
200	`OK`	HTTP/1.1 RFC 7231, Section 6.3.1
201	`CREATED`	HTTP/1.1 RFC 7231, Section 6.3.2
202	`ACCEPTED`	HTTP/1.1 RFC 7231, Section 6.3.3
203	`NON_AUTHORITATIVE_INFORMATION`	HTTP/1.1 RFC 7231, Section 6.3.4
204	`NO_CONTENT`	HTTP/1.1 RFC 7231, Section 6.3.5
205	`RESET_CONTENT`	HTTP/1.1 RFC 7231, Section 6.3.6
206	`PARTIAL_CONTENT`	HTTP/1.1 RFC 7233, Section 4.1
207	`MULTI_STATUS`	WebDAV RFC 4918, Section 11.1
208	`ALREADY_REPORTED`	WebDAV Binding Extensions RFC 5842, Section 7.1 (Experimental)
226	`IM_USED`	Delta Encoding in HTTP RFC 3229, Section 10.4.1
300	`MULTIPLE_CHOICES`	HTTP/1.1 RFC 7231, Section 6.4.1
301	`MOVED_PERMANENTLY`	HTTP/1.1 RFC 7231, Section 6.4.2
302	`FOUND`	HTTP/1.1 RFC 7231, Section 6.4.3
303	`SEE_OTHER`	HTTP/1.1 RFC 7231, Section 6.4.4
304	`NOT_MODIFIED`	HTTP/1.1 RFC 7232, Section 4.1
305	`USE_PROXY`	HTTP/1.1 RFC 7231, Section 6.4.5
306	`TEMPORARY_REDIRECT`	HTTP/1.1 RFC 7231, Section 6.4.7
308	`PERMANENT_REDIRECT`	Permanent Redirect RFC 7238, Section 3 (Experimental)
400	`BAD_REQUEST`	HTTP/1.1 RFC 7231, Section 6.5.1
401	`UNAUTHORIZED`	HTTP/1.1 Authentication RFC 7235, Section 3.1
402	`PAYMENT_REQUIRED`	HTTP/1.1 RFC 7231, Section 6.5.2

HTTP/1.1	RFC 7231, Section 6.5.3
HTTP/1.1	RFC 7231, Section 6.5.4
HTTP/1.1	RFC 7231, Section 6.5.5
HTTP/1.1	RFC 7231, Section 6.5.6
HTTP/1.1 Authentication	RFC 7235, Section 3.2
HTTP/1.1	RFC 7231, Section 6.5.7
HTTP/1.1	RFC 7231, Section 6.5.8
HTTP/1.1	RFC 7231, Section 6.5.9
HTTP/1.1	RFC 7231, Section 6.5.10
HTTP/1.1	RFC 7231, Section 4.2
HTTP/1.1	RFC 7231, Section 6.5.11
HTTP/1.1	RFC 7231, Section 6.5.12
HTTP/1.1	RFC 7231, Section 6.5.13
HTTP/1.1 Range Requests	RFC 7233, Section 4.4
HTTP/1.1	RFC 7231, Section 6.5.14
HTCPCP/1.0	RFC 2324, Section 2.3.2
HTTP/2	RFC 7540, Section 9.1.2
WebDAV	RFC 4918, Section 11.2
WebDAV	RFC 4918, Section 11.3
WebDAV	RFC 4918, Section 11.4
Using Early Data in HTTP	RFC 8470
HTTP/1.1	RFC 7231, Section 6.5.15
Additional HTTP Status Codes	RFC 6585
Additional HTTP Status Codes	RFC 6585
Additional HTTP Status Codes	RFC 6585
An HTTP Status Code to Report Legal Obstacles	RFC 7725
HTTP/1.1	RFC 7231, Section 6.6.1
HTTP/1.1	RFC 7231, Section 6.6.2
HTTP/1.1	RFC 7231, Section 6.6.3
HTTP/1.1	RFC 7231, Section 6.6.4
HTTP/1.1	RFC 7231, Section 6.6.5
HTTP/1.1	RFC 7231, Section 6.6.6
Transparent Content Negotiation in HTTP	RFC 2295, Section 8.1 (Experimental)
WebDAV	RFC 4918, Section 11.5
WebDAV Binding Extensions	RFC 5842, Section 7.2 (Experimental)
An HTTP Extension Framework	RFC 2774, Section 7 (Experimental)
Additional HTTP Status Codes	RFC 6585, Section 6

In order to preserve backwards compatibility, enum values are also present in the **`http.client`** module in the form of constants. The enum name is equal to the constant name (i.e. `http.HTTPStatus.OK` is also available as `http.client.OK`).

Changed in version 3.7: Added `421 MISDIRECTED_REQUEST` status code.

New in version 3.8: Added `451 UNAVAILABLE_FOR_LEGAL_REASONS` status code.

New in version 3.9: Added `103 EARLY_HINTS`, `418 IM_A_TEAPOT` and `425 TOO_EARLY` status codes.

class http.HTTPMethod

New in version 3.11.

A subclass of **`enum.StrEnum`** that defines a set of HTTP methods and descriptions written in English.

Usage:

```
>>> from http import HTTPMethod
>>>
>>> HTTPMethod.GET
<HTTPMethod.GET>
>>> HTTPMethod.GET == 'GET'
True
>>> HTTPMethod.GET.value
'GET'
>>> HTTPMethod.GET.description
'Retrieve the target.'
>>> list(HTTPMethod)
[<HTTPMethod.CONNECT>,
 <HTTPMethod.DELETE>,
 <HTTPMethod.GET>,
 <HTTPMethod.HEAD>,
 <HTTPMethod.OPTIONS>,
 <HTTPMethod.PATCH>,
 <HTTPMethod.POST>,
```

```
    <HTTPMethod.PUT>,
    <HTTPMethod.TRACE>]
```

HTTP methods

Supported, IANA-registered methods [https://www.iana.org/assignments/http-methods/http-methods.xhtml] available in **`http.HTTPMethod`** are:

Method	Name
GET	HTTP/1.1 **RFC 7231**, Section 4.3.1
HEAD	HTTP/1.1 **RFC 7231**, Section 4.3.2
POST	HTTP/1.1 **RFC 7231**, Section 4.3.3
PUT	HTTP/1.1 **RFC 7231**, Section 4.3.4
DELETE	HTTP/1.1 **RFC 7231**, Section 4.3.5
CONNECT	HTTP/1.1 **RFC 7231**, Section 4.3.6
OPTIONS	HTTP/1.1 **RFC 7231**, Section 4.3.7
TRACE	HTTP/1.1 **RFC 7231**, Section 4.3.8
PATCH	HTTP/1.1 **RFC 5789**

`http.client` — HTTP protocol client

Source code: Lib/http/client.py [https://github.com/python/cpython/tree/3.11/Lib/http/client.py]

This module defines classes that implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module `urllib.request` uses it to handle URLs that use HTTP and HTTPS.

See also

The Requests package [https://requests.readthedocs.io/en/master/] is recommended for a higher-level HTTP client interface.

Note

HTTPS support is only available if Python was compiled with SSL support (through the `ssl` module).

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The module provides the following classes:

class http.client.HTTPConnection(*host*, *port*=*None*, [*timeout*,]*source_address*=*None*, *blocksize*=*8192*)

An `HTTPConnection` instance represents one transaction

with an HTTP server. It should be instantiated by passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form `host:port`, else the default HTTP port (80) is used. If the optional *timeout* parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional *source_address* parameter may be a tuple of a (host, port) to use as the source address the HTTP connection is made from. The optional *blocksize* parameter sets the buffer size in bytes for sending a file-like message body.

For example, the following calls all create instances that connect to the server at the same host and port:

```
>>> h1 = http.client.HTTPConnection('www.python.org
>>> h2 = http.client.HTTPConnection('www.python.org
>>> h3 = http.client.HTTPConnection('www.python.org
>>> h4 = http.client.HTTPConnection('www.python.org
```

Changed in version 3.2: source_address was added.

Changed in version 3.4: The *strict* parameter was removed. HTTP 0.9-style "Simple Responses" are no longer supported.

Changed in version 3.7: blocksize parameter was added.

class http.client.HTTPSConnection(*host*, *port*=*None*, *key_file*=*None*, *cert_file*=*None*, [*timeout*,]*source_address*=*None*, *, *context*=*None*, *check_hostname*=*None*, *blocksize*=*8192*)

A subclass of **`HTTPConnection`** that uses SSL for communication with secure servers. Default port is `443`. If *context* is specified, it must be a **`ssl.SSLContext`** instance describing the various SSL options.

Please read Security considerations for more information on best practices.

Changed in version 3.2: source_address, *context* and *check_hostname* were added.

Changed in version 3.2: This class now supports HTTPS virtual hosts if possible (that is, if **ssl.HAS_SNI** is true).

Changed in version 3.4: The *strict* parameter was removed. HTTP 0.9-style "Simple Responses" are no longer supported.

Changed in version 3.4.3: This class now performs all the necessary certificate and hostname checks by default. To revert to the previous, unverified, behavior **ssl._create_unverified_context()** can be passed to the *context* parameter.

Changed in version 3.8: This class now enables TLS 1.3 **ssl.SSLContext.post_handshake_auth** for the default *context* or when *cert_file* is passed with a custom *context*.

Changed in version 3.10: This class now sends an ALPN extension with protocol indicator `http/1.1` when no *context* is given. Custom *context* should set ALPN protocols with **set_alpn_protocol()**.

Deprecated since version 3.6: key_file and *cert_file* are deprecated in favor of *context*. Please use **ssl.SSLContext.load_cert_chain()** instead, or let **ssl.create_default_context()** select the system's trusted CA certificates for you.

The *check_hostname* parameter is also deprecated; the **ssl.SSLContext.check_hostname** attribute of *context* should be used instead.

class http.client.HTTPResponse(*sock*, *debuglevel=0*, *method=None*, *url=None*)

Class whose instances are returned upon successful connection. Not instantiated directly by user.

Changed in version 3.4: The *strict* parameter was removed. HTTP 0.9 style "Simple Responses" are no longer supported.

This module provides the following function:

http.client.parse_headers(*fp*)

Parse the headers from a file pointer *fp* representing a HTTP request/response. The file has to be a **`BufferedIOBase`** reader (i.e. not text) and must provide a valid **RFC 2822** [https://datatracker.ietf.org/doc/html/rfc2822.html] style header.

This function returns an instance of **`http.client.HTTPMessage`** that holds the header fields, but no payload (the same as **`HTTPResponse.msg`** and **`http.server.BaseHTTPRequestHandler.headers`**). After returning, the file pointer *fp* is ready to read the HTTP body.

Note

`parse_headers()` does not parse the start-line of a HTTP message; it only parses the `Name: value` lines. The file has to be ready to read these field lines, so the first line should already be consumed before calling the function.

The following exceptions are raised as appropriate:

exception http.client.HTTPException

The base class of the other exceptions in this module. It is a subclass of **`Exception`**.

exception http.client.NotConnected

A subclass of **`HTTPException`**.

exception http.client.InvalidURL

A subclass of **`HTTPException`**, raised if a port is given and is either non-numeric or empty.

exception http.client.UnknownProtocol

A subclass of **`HTTPException`**.

exception http.client.UnknownTransferEncoding

A subclass of **HTTPException**.

exception http.client.UnimplementedFileMode

A subclass of **HTTPException**.

exception http.client.IncompleteRead

A subclass of **HTTPException**.

exception http.client.ImproperConnectionState

A subclass of **HTTPException**.

exception http.client.CannotSendRequest

A subclass of **ImproperConnectionState**.

exception http.client.CannotSendHeader

A subclass of **ImproperConnectionState**.

exception http.client.ResponseNotReady

A subclass of **ImproperConnectionState**.

exception http.client.BadStatusLine

A subclass of **HTTPException**. Raised if a server responds with a HTTP status code that we don't understand.

exception http.client.LineTooLong

A subclass of **HTTPException**. Raised if an excessively long line is received in the HTTP protocol from the server.

exception http.client.RemoteDisconnected

A subclass of **ConnectionResetError** and **BadStatusLine**. Raised by **HTTPConnection.getresponse()** when the attempt to read the response results in no data read from the connection, indicating that the remote end has closed the connection.

New in version 3.5: Previously, **BadStatusLine**`('')` was

raised.

The constants defined in this module are:

http.client.HTTP_PORT
: The default port for the HTTP protocol (always `80`).

http.client.HTTPS_PORT
: The default port for the HTTPS protocol (always `443`).

http.client.responses
: This dictionary maps the HTTP 1.1 status codes to the W3C names.

  Example: `http.client.responses[http.client.NOT_FOUND]` is `'Not Found'`.

See HTTP status codes for a list of HTTP status codes that are available in this module as constants.

HTTPConnection Objects

`HTTPConnection` instances have the following methods:

HTTPConnection.request(*method*, *url*, *body*=*None*, *headers*={}, *, *encode_chunked*=*False*)
: This will send a request to the server using the HTTP request method *method* and the selector *url*.

  If *body* is specified, the specified data is sent after the headers are finished. It may be a **`str`**, a bytes-like object, an open file object, or an iterable of **`bytes`**. If *body* is a string, it is encoded as ISO-8859-1, the default for HTTP. If it is a bytes-like object, the bytes are sent as is. If it is a file object, the contents of the file is sent; this file object should support at least the `read()` method. If the file object is an instance of **`io.TextIOBase`**, the data returned by the `read()` method

will be encoded as ISO-8859-1, otherwise the data returned by `read()` is sent as is. If *body* is an iterable, the elements of the iterable are sent as is until the iterable is exhausted.

The *headers* argument should be a mapping of extra HTTP headers to send with the request.

If *headers* contains neither Content-Length nor Transfer-Encoding, but there is a request body, one of those header fields will be added automatically. If *body* is `None`, the Content-Length header is set to `0` for methods that expect a body (`PUT`, `POST`, and `PATCH`). If *body* is a string or a bytes-like object that is not also a file, the Content-Length header is set to its length. Any other type of *body* (files and iterables in general) will be chunk-encoded, and the Transfer-Encoding header will automatically be set instead of Content-Length.

The *encode_chunked* argument is only relevant if Transfer-Encoding is specified in *headers*. If *encode_chunked* is `False`, the HTTPConnection object assumes that all encoding is handled by the calling code. If it is `True`, the body will be chunk-encoded.

Note

Chunked transfer encoding has been added to the HTTP protocol version 1.1. Unless the HTTP server is known to handle HTTP 1.1, the caller must either specify the Content-Length, or must pass a **`str`** or bytes-like object that is not also a file as the body representation.

New in version 3.2: body can now be an iterable.

Changed in version 3.6: If neither Content-Length nor Transfer-Encoding are set in *headers*, file and iterable *body* objects are now chunk-encoded. The *encode_chunked* argument was added. No attempt is made to determine the Content-Length for file objects.

HTTPConnection.getresponse()

Should be called after a request is sent to get the response from the server. Returns an **HTTPResponse** instance.

Note

Note that you must have read the whole response before you can send a new request to the server.

Changed in version 3.5: If a **ConnectionError** or subclass is raised, the **HTTPConnection** object will be ready to reconnect when a new request is sent.

HTTPConnection.set_debuglevel(*level*)

Set the debugging level. The default debug level is `0`, meaning no debugging output is printed. Any value greater than `0` will cause all currently defined debug output to be printed to stdout. The `debuglevel` is passed to any new **HTTPResponse** objects that are created.

New in version 3.1.

HTTPConnection.set_tunnel(*host*, *port*=*None*, *headers*=*None*)

Set the host and the port for HTTP Connect Tunnelling. This allows running the connection through a proxy server.

The host and port arguments specify the endpoint of the tunneled connection (i.e. the address included in the CONNECT request, *not* the address of the proxy server).

The headers argument should be a mapping of extra HTTP headers to send with the CONNECT request.

For example, to tunnel through a HTTPS proxy server running locally on port 8080, we would pass the address of the proxy to the **HTTPSConnection** constructor, and the address of the host that we eventually want to reach to the **set_tunnel()** method:

```
>>> import http.client
```

```
>>> conn = http.client.HTTPSConnection("localhost",
>>> conn.set_tunnel("www.python.org")
>>> conn.request("HEAD","/index.html")
```

New in version 3.2.

HTTPConnection.connect()

Connect to the server specified when the object was created. By default, this is called automatically when making a request if the client does not already have a connection.

Raises an auditing event `http.client.connect` with arguments `self`, `host`, `port`.

HTTPConnection.close()

Close the connection to the server.

HTTPConnection.blocksize

Buffer size in bytes for sending a file-like message body.

New in version 3.7.

As an alternative to using the **`request()`** method described above, you can also send your request step by step, by using the four functions below.

HTTPConnection.putrequest(*method*, *url*, *skip_host*=*False*, *skip_accept_encoding*=*False*)

This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the *method* string, the *url* string, and the HTTP version (`HTTP/1.1`). To disable automatic sending of `Host:` or `Accept-Encoding:` headers (for example to accept additional content encodings), specify *skip_host* or *skip_accept_encoding* with non-False values.

HTTPConnection.putheader(*header*, *argument*[, ...])

Send an **RFC 822** [https://datatracker.ietf.org/doc/html/rfc822.html]-

style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

HTTPConnection.endheaders(*message_body=None*, *, *encode_chunked=False*)

Send a blank line to the server, signalling the end of the headers. The optional *message_body* argument can be used to pass a message body associated with the request.

If *encode_chunked* is `True`, the result of each iteration of *message_body* will be chunk-encoded as specified in **RFC 7230** [https://datatracker.ietf.org/doc/html/rfc7230.html], Section 3.3.1. How the data is encoded is dependent on the type of *message_body*. If *message_body* implements the buffer interface the encoding will result in a single chunk. If *message_body* is a **`collections.abc.Iterable`**, each iteration of *message_body* will result in a chunk. If *message_body* is a file object, each call to `.read()` will result in a chunk. The method automatically signals the end of the chunk-encoded data immediately after *message_body*.

Note

Due to the chunked encoding specification, empty chunks yielded by an iterator body will be ignored by the chunk-encoder. This is to avoid premature termination of the read of the request by the target server due to malformed encoding.

New in version 3.6: Chunked encoding support. The *encode_chunked* parameter was added.

HTTPConnection.send(*data*)

Send data to the server. This should be used directly only after the **`endheaders()`** method has been called and before **`getresponse()`** is called.

Raises an auditing event `http.client.send` with arguments `self`, `data`.

HTTPResponse Objects

An **`HTTPResponse`** instance wraps the HTTP response from the server. It provides access to the request headers and the entity body. The response is an iterable object and can be used in a with statement.

Changed in version 3.5: The **`io.BufferedIOBase`** interface is now implemented and all of its reader operations are supported.

HTTPResponse.read([*amt*])

Reads and returns the response body, or up to the next *amt* bytes.

HTTPResponse.readinto(*b*)

Reads up to the next len(b) bytes of the response body into the buffer *b*. Returns the number of bytes read.

New in version 3.3.

HTTPResponse.getheader(*name*, *default*=*None*)

Return the value of the header *name*, or *default* if there is no header matching *name*. If there is more than one header with the name *name*, return all of the values joined by ', '. If *default* is any iterable other than a single string, its elements are similarly returned joined by commas.

HTTPResponse.getheaders()

Return a list of (header, value) tuples.

HTTPResponse.fileno()

Return the `fileno` of the underlying socket.

HTTPResponse.msg

A **http.client.HTTPMessage** instance containing the response headers. **http.client.HTTPMessage** is a subclass of **email.message.Message**.

HTTPResponse.version

HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

HTTPResponse.url

URL of the resource retrieved, commonly used to determine if a redirect was followed.

HTTPResponse.headers

Headers of the response in the form of an **email.message.EmailMessage** instance.

HTTPResponse.status

Status code returned by server.

HTTPResponse.reason

Reason phrase returned by server.

HTTPResponse.debuglevel

A debugging hook. If **debuglevel** is greater than zero, messages will be printed to stdout as the response is read and parsed.

HTTPResponse.closed

Is `True` if the stream is closed.

HTTPResponse.geturl()

Deprecated since version 3.9: Deprecated in favor of **url**.

HTTPResponse.info()

Deprecated since version 3.9: Deprecated in favor of **headers**.

HTTPResponse.getstatus()

Deprecated since version 3.9: Deprecated in favor of **status**.

Examples

Here is an example session that uses the `GET` method:

```
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> print(r1.status, r1.reason)
200 OK
>>> data1 = r1.read()  # This will return entire content
>>> # The following example demonstrates reading data in
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> while chunk := r1.read(200):
...     print(repr(chunk))
b'<!doctype html>\n<!--[if"...
...
>>> # Example of an invalid request
>>> conn = http.client.HTTPSConnection("docs.python.org"
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print(r2.status, r2.reason)
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the `HEAD` method. Note that the `HEAD` method never returns any data.

```
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("HEAD", "/")
>>> res = conn.getresponse()
>>> print(res.status, res.reason)
```

```
200 OK
>>> data = res.read()
>>> print(len(data))
0
>>> data == b''
True
```

Here is an example session that uses the `POST` method:

```
>>> import http.client, urllib.parse
>>> params = urllib.parse.urlencode({'@number': 12524, '
>>> headers = {"Content-type": "application/x-www-form-u
...            "Accept": "text/plain"}
>>> conn = http.client.HTTPConnection("bugs.python.org")
>>> conn.request("POST", "", params, headers)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
302 Found
>>> data = response.read()
>>> data
b'Redirecting to <a href="https://bugs.python.org/issue1
>>> conn.close()
```

Client side HTTP `PUT` requests are very similar to `POST` requests. The difference lies only on the server side where HTTP servers will allow resources to be created via `PUT` requests. It should be noted that custom HTTP methods are also handled in **`urllib.request.Request`** by setting the appropriate method attribute. Here is an example session that uses the `PUT` method:

```
>>> # This creates an HTTP request
>>> # with the content of BODY as the enclosed represent
>>> # for the resource http://localhost:8080/file
...
>>> import http.client
>>> BODY = "***filecontents***"
>>> conn = http.client.HTTPConnection("localhost", 8080)
>>> conn.request("PUT", "/file", BODY)
>>> response = conn.getresponse()
```

```
>>> print(response.status, response.reason)
200, OK
```

HTTPMessage Objects

An **`http.client.HTTPMessage`** instance holds the headers from an HTTP response. It is implemented using the **`email.message.Message`** class.

`ftplib` — FTP protocol client

Source code: Lib/ftplib.py [https://github.com/python/cpython/tree/3.11/Lib/ftplib.py]

This module defines the class `FTP` and a few related items. The `FTP` class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other FTP servers. It is also used by the module `urllib.request` to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see internet RFC 959 [https://datatracker.ietf.org/doc/html/rfc959.html].

The default encoding is UTF-8, following RFC 2640 [https://datatracker.ietf.org/doc/html/rfc2640.html].

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Here's a sample session using the `ftplib` module:

```
>>> from ftplib import FTP
>>> ftp = FTP('ftp.us.debian.org')  # connect to host, c
>>> ftp.login()                     # user anonymous, pa
'230 Login successful.'
>>> ftp.cwd('debian')               # change into "debia
'250 Directory successfully changed.'
>>> ftp.retrlines('LIST')           # list directory cor
-rw-rw-r--    1 1176     1176         1063 Jun 15 10:18
...
drwxr-sr-x    5 1176     1176         4096 Dec 19  2000
drwxr-sr-x    4 1176     1176         4096 Nov 17  2008
```

```
drwxr-xr-x    3 1176     1176         4096 Oct 10  2012
'226 Directory send OK.'
>>> with open('README', 'wb') as fp:
>>>     ftp.retrbinary('RETR README', fp.write)
'226 Transfer complete.'
>>> ftp.quit()
'221 Goodbye.'
```

The module defines the following items:

class ftplib.FTP(*host*=*''*, *user*=*''*, *passwd*=*''*, *acct*=*''*, *timeout*=*None*, *source_address*=*None*, ***, *encoding*=*'utf-8'*)

Return a new instance of the **FTP** class. When *host* is given, the method call `connect(host)` is made. When *user* is given, additionally the method call `login(user, passwd, acct)` is made (where *passwd* and *acct* default to the empty string when not given). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used). *source_address* is a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting. The *encoding* parameter specifies the encoding for directories and filenames.

The **FTP** class supports the **with** statement, e.g.:

```
>>> from ftplib import FTP
>>> with FTP("ftp1.at.proftpd.org") as ftp:
...     ftp.login()
...     ftp.dir()
...
'230 Anonymous login ok, restrictions apply.'
dr-xr-xr-x   9 ftp      ftp           154 May  6 10
dr-xr-xr-x   9 ftp      ftp           154 May  6 10
dr-xr-xr-x   5 ftp      ftp          4096 May  6 10
dr-xr-xr-x   3 ftp      ftp            18 Jul 10  2
>>>
```

Changed in version 3.2: Support for the **with** statement was

added.

Changed in version 3.3: source_address parameter was added.

Changed in version 3.9: If the *timeout* parameter is set to be zero, it will raise a `ValueError` to prevent the creation of a non-blocking socket. The *encoding* parameter was added, and the default was changed from Latin-1 to UTF-8 to follow **RFC 2640** [https://datatracker.ietf.org/doc/html/rfc2640.html].

class ftplib.FTP_TLS(*host=''*, *user=''*, *passwd=''*, *acct=''*, *keyfile=None*, *certfile=None*, *context=None*, *timeout=None*, *source_address=None*, ***, *encoding='utf-8'*)

A `FTP` subclass which adds TLS support to FTP as described in **RFC 4217** [https://datatracker.ietf.org/doc/html/rfc4217.html]. Connect as usual to port 21 implicitly securing the FTP control connection before authenticating. Securing the data connection requires the user to explicitly ask for it by calling the `prot_p()` method. *context* is a `ssl.SSLContext` object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

keyfile and *certfile* are a legacy alternative to *context* – they can point to PEM-formatted private key and certificate chain files (respectively) for the SSL connection.

New in version 3.2.

Changed in version 3.3: source_address parameter was added.

Changed in version 3.4: The class now supports hostname check with `ssl.SSLContext.check_hostname` and *Server Name Indication* (see `ssl.HAS_SNI`).

Deprecated since version 3.6: keyfile and *certfile* are deprecated in favor of *context*. Please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system's

trusted CA certificates for you.

Changed in version 3.9: If the *timeout* parameter is set to be zero, it will raise a **ValueError** to prevent the creation of a non-blocking socket. The *encoding* parameter was added, and the default was changed from Latin-1 to UTF-8 to follow **RFC 2640** [https://datatracker.ietf.org/doc/html/rfc2640.html].

Here's a sample session using the **FTP_TLS** class:

```
>>> ftps = FTP_TLS('ftp.pureftpd.org')
>>> ftps.login()
'230 Anonymous user logged in'
>>> ftps.prot_p()
'200 Data protection level set to "private"'
>>> ftps.nlst()
['6jack', 'OpenBSD', 'antilink', 'blogbench', 'bsdc
```

exception ftplib.error_reply

Exception raised when an unexpected reply is received from the server.

exception ftplib.error_temp

Exception raised when an error code signifying a temporary error (response codes in the range 400–499) is received.

exception ftplib.error_perm

Exception raised when an error code signifying a permanent error (response codes in the range 500–599) is received.

exception ftplib.error_proto

Exception raised when a reply is received from the server that does not fit the response specifications of the File Transfer Protocol, i.e. begin with a digit in the range 1–5.

ftplib.all_errors

The set of all exceptions (as a tuple) that methods of **FTP** instances may raise as a result of problems with the FTP

connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed above as well as **OSError** and **EOFError**.

See also

Module netrc
Parser for the `.netrc` file format. The file `.netrc` is typically used by FTP clients to load user authentication information before prompting the user.

FTP Objects

Several methods are available in two flavors: one for handling text files and another for binary files. These are named for the command which is used followed by `lines` for the text version or `binary` for the binary version.

FTP instances have the following methods:

FTP.set_debuglevel(*level*)
Set the instance's debugging level. This controls the amount of debugging output printed. The default, `0`, produces no debugging output. A value of `1` produces a moderate amount of debugging output, generally a single line per request. A value of `2` or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

FTP.connect(*host='', port=0, timeout=None, source_address=None*)
Connect to the given host and port. The default port number is `21`, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made. The optional *timeout* parameter specifies a timeout in seconds for the connection

attempt. If no *timeout* is passed, the global default timeout setting will be used. *source_address* is a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting.

Raises an auditing event `ftplib.connect` with arguments `self, host, port`.

Changed in version 3.3: source_address parameter was added.

FTP.getwelcome()

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

FTP.login(*user='anonymous', passwd='', acct=''*)

Log in as the given *user*. The *passwd* and *acct* parameters are optional and default to the empty string. If no *user* is specified, it defaults to `'anonymous'`. If *user* is `'anonymous'`, the default *passwd* is `'anonymous@'`. This function should be called only once for each instance, after a connection has been established; it should not be called at all if a host and user were given when the instance was created. Most FTP commands are only allowed after the client has logged in. The *acct* parameter supplies "accounting information"; few systems implement this.

FTP.abort()

Abort a file transfer that is in progress. Using this does not always work, but it's worth a try.

FTP.sendcmd(*cmd*)

Send a simple command string to the server and return the response string.

Raises an auditing event `ftplib.sendcmd` with arguments `self, cmd`.

FTP.voidcmd(*cmd*)

Send a simple command string to the server and handle the response. Return nothing if a response code corresponding to success (codes in the range 200–299) is received. Raise **`error_reply`** otherwise.

Raises an auditing event `ftplib.sendcmd` with arguments `self`, `cmd`.

FTP.retrbinary(*cmd*, *callback*, *blocksize*=*8192*, *rest*=*None*)

Retrieve a file in binary transfer mode. *cmd* should be an appropriate `RETR` command: `'RETR filename'`. The *callback* function is called for each block of data received, with a single bytes argument giving the data block. The optional *blocksize* argument specifies the maximum chunk size to read on the low-level socket object created to do the actual transfer (which will also be the largest size of the data blocks passed to *callback*). A reasonable default is chosen. *rest* means the same thing as in the **`transfercmd()`** method.

FTP.retrlines(*cmd*, *callback*=*None*)

Retrieve a file or directory listing in the encoding specified by the *encoding* parameter at initialization. *cmd* should be an appropriate `RETR` command (see **`retrbinary()`**) or a command such as `LIST` or `NLST` (usually just the string `'LIST'`). `LIST` retrieves a list of files and information about those files. `NLST` retrieves a list of file names. The *callback* function is called for each line with a string argument containing the line with the trailing CRLF stripped. The default *callback* prints the line to `sys.stdout`.

FTP.set_pasv(*val*)

Enable “passive” mode if *val* is true, otherwise disable passive mode. Passive mode is on by default.

FTP.storbinary(*cmd*, *fp*, *blocksize*=*8192*, *callback*=*None*, *rest*=*None*)

Store a file in binary transfer mode. *cmd* should be an appropriate `STOR` command: `"STOR filename"`. *fp* is a file object (opened in binary mode) which is read until EOF using its **`read()`** method in blocks of size *blocksize* to provide the data to be stored. The *blocksize* argument defaults to 8192. *callback* is an optional single parameter callable that is called on each block of data after it is sent. *rest* means the same thing as in the **`transfercmd()`** method.

Changed in version 3.2: rest parameter added.

FTP.storlines(*cmd*, *fp*, *callback*=*None*)

Store a file in line mode. *cmd* should be an appropriate `STOR` command (see **`storbinary()`**). Lines are read until EOF from the file object *fp* (opened in binary mode) using its **`readline()`** method to provide the data to be stored. *callback* is an optional single parameter callable that is called on each line after it is sent.

FTP.transfercmd(*cmd*, *rest*=*None*)

Initiate a transfer over the data connection. If the transfer is active, send an `EPRT` or `PORT` command and the transfer command specified by *cmd*, and accept the connection. If the server is passive, send an `EPSV` or `PASV` command, connect to it, and start the transfer command. Either way, return the socket for the connection.

If optional *rest* is given, a `REST` command is sent to the server, passing *rest* as an argument. *rest* is usually a byte offset into the requested file, telling the server to restart sending the file's bytes at the requested offset, skipping over the initial bytes. Note however that the **`transfercmd()`** method converts *rest* to a string with the *encoding* parameter specified at initialization, but no check is performed on the string's contents. If the server does not recognize the `REST` command, an **`error_reply`** exception will be raised. If this happens, simply call **`transfercmd()`** without a *rest* argument.

FTP.ntransfercmd(*cmd*, *rest*=*None*)

Like **transfercmd()**, but returns a tuple of the data connection and the expected size of the data. If the expected size could not be computed, `None` will be returned as the expected size. *cmd* and *rest* means the same thing as in **transfercmd()**.

FTP.mlsd(*path*='', *facts*=[])

List a directory in a standardized format by using `MLSD` command (**RFC 3659** [https://datatracker.ietf.org/doc/html/rfc3659.html]). If *path* is omitted the current directory is assumed. *facts* is a list of strings representing the type of information desired (e.g. `["type", "size", "perm"]`). Return a generator object yielding a tuple of two elements for every file found in path. First element is the file name, the second one is a dictionary containing facts about the file name. Content of this dictionary might be limited by the *facts* argument but server is not guaranteed to return all requested facts.

New in version 3.3.

FTP.nlst(*argument*[, ...])

Return a list of file names as returned by the `NLST` command. The optional *argument* is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the `NLST` command.

Note

If your server supports the command, **mlsd()** offers a better API.

FTP.dir(*argument*[, ...])

Produce a directory listing as returned by the `LIST` command, printing it to standard output. The optional *argument* is a directory to list (default is the current server

directory). Multiple arguments can be used to pass non-standard options to the `LIST` command. If the last argument is a function, it is used as a *callback* function as for **`retrlines()`**; the default prints to `sys.stdout`. This method returns `None`.

Note

If your server supports the command, **`mlsd()`** offers a better API.

FTP.rename(*fromname*, *toname*)

Rename file *fromname* on the server to *toname*.

FTP.delete(*filename*)

Remove the file named *filename* from the server. If successful, returns the text of the response, otherwise raises **`error_perm`** on permission errors or **`error_reply`** on other errors.

FTP.cwd(*pathname*)

Set the current directory on the server.

FTP.mkd(*pathname*)

Create a new directory on the server.

FTP.pwd()

Return the pathname of the current directory on the server.

FTP.rmd(*dirname*)

Remove the directory named *dirname* on the server.

FTP.size(*filename*)

Request the size of the file named *filename* on the server. On success, the size of the file is returned as an integer, otherwise

`None` is returned. Note that the `SIZE` command is not standardized, but is supported by many common server implementations.

FTP.quit()

Send a `QUIT` command to the server and close the connection. This is the "polite" way to close a connection, but it may raise an exception if the server responds with an error to the `QUIT` command. This implies a call to the **`close()`** method which renders the **`FTP`** instance useless for subsequent calls (see below).

FTP.close()

Close the connection unilaterally. This should not be applied to an already closed connection such as after a successful call to **`quit()`**. After this call the **`FTP`** instance should not be used any more (after a call to **`close()`** or **`quit()`** you cannot reopen the connection by issuing another **`login()`** method).

FTP_TLS Objects

`FTP_TLS` class inherits from **`FTP`**, defining these additional objects:

FTP_TLS.ssl_version

The SSL version to use (defaults to **`ssl.PROTOCOL_SSLv23`**).

FTP_TLS.auth()

Set up a secure control connection by using TLS or SSL, depending on what is specified in the **`ssl_version`** attribute.

Changed in version 3.4: The method now supports hostname check with **`ssl.SSLContext.check_hostname`** and *Server Name Indication* (see **`ssl.HAS_SNI`**).

FTP_TLS.ccc()

Revert control channel back to plaintext. This can be useful to take advantage of firewalls that know how to handle NAT with non-secure FTP without opening fixed ports.

New in version 3.3.

FTP_TLS.prot_p()

Set up secure data connection.

FTP_TLS.prot_c()

Set up clear text data connection.

poplib — POP3 protocol client

Source code: Lib/poplib.py [https://github.com/python/cpython/tree/3.11/Lib/poplib.py]

This module defines a class, **POP3**, which encapsulates a connection to a POP3 server and implements the protocol as defined in **RFC 1939** [https://datatracker.ietf.org/doc/html/rfc1939.html]. The **POP3** class supports both the minimal and optional command sets from **RFC 1939** [https://datatracker.ietf.org/doc/html/rfc1939.html]. The **POP3** class also supports the `STLS` command introduced in **RFC 2595** [https://datatracker.ietf.org/doc/html/rfc2595.html] to enable encrypted communication on an already established connection.

Additionally, this module provides a class **POP3_SSL**, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the **imaplib.IMAP4** class, as IMAP servers tend to be better implemented.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

The **poplib** module provides two classes:

class poplib.POP3(*host*, *port*=*POP3_PORT*[, *timeout*])

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If *port*

is omitted, the standard POP3 port (110) is used. The optional *timeout* parameter specifies a timeout in seconds for the connection attempt (if not specified, the global default timeout setting will be used).

Raises an auditing event `poplib.connect` with arguments `self, host, port`.

All commands will raise an auditing event `poplib.putline` with arguments `self` and `line`, where `line` is the bytes about to be sent to the remote host.

Changed in version 3.9: If the *timeout* parameter is set to be zero, it will raise a **`ValueError`** to prevent the creation of a non-blocking socket.

class poplib.POP3_SSL(*host*, *port*=*POP3_SSL_PORT*, *keyfile*=*None*, *certfile*=*None*, *timeout*=*None*, *context*=*None*)

This is a subclass of **`POP3`** that connects to the server over an SSL encrypted socket. If *port* is not specified, 995, the standard POP3-over-SSL port is used. *timeout* works as in the **`POP3`** constructor. *context* is an optional **`ssl.SSLContext`** object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

keyfile and *certfile* are a legacy alternative to *context* - they can point to PEM-formatted private key and certificate chain files, respectively, for the SSL connection.

Raises an auditing event `poplib.connect` with arguments `self, host, port`.

All commands will raise an auditing event `poplib.putline` with arguments `self` and `line`, where `line` is the bytes about to be sent to the remote host.

Changed in version 3.2: context parameter added.

Changed in version 3.4: The class now supports hostname check with `ssl.SSLContext.check_hostname` and *Server Name Indication* (see `ssl.HAS_SNI`).

Deprecated since version 3.6: keyfile and *certfile* are deprecated in favor of *context*. Please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system's trusted CA certificates for you.

Changed in version 3.9: If the *timeout* parameter is set to be zero, it will raise a `ValueError` to prevent the creation of a non-blocking socket.

One exception is defined as an attribute of the `poplib` module:

exception poplib.error_proto

Exception raised on any errors from this module (errors from `socket` module are not caught). The reason for the exception is passed to the constructor as a string.

See also

Module `imaplib`
The standard Python IMAP module.

Frequently Asked Questions About Fetchmail [http://www.catb.org/~esr/fetchmail/fetchmail-FAQ.html]
The FAQ for the **fetchmail** POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.

POP3 Objects

All POP3 commands are represented by methods of the same name, in lowercase; most return the response text sent by the server.

A **POP3** instance has the following methods:

POP3.set_debuglevel(*level*)

Set the instance's debugging level. This controls the amount of debugging output printed. The default, `0`, produces no debugging output. A value of `1` produces a moderate amount of debugging output, generally a single line per request. A value of `2` or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

POP3.getwelcome()

Returns the greeting string sent by the POP3 server.

POP3.capa()

Query the server's capabilities as specified in **RFC 2449** [https://datatracker.ietf.org/doc/html/rfc2449.html]. Returns a dictionary in the form `{'name': ['param'...]}`.

New in version 3.4.

POP3.user(*username*)

Send user command, response should indicate that a password is required.

POP3.pass_(*password*)

Send password, response includes message count and mailbox size. Note: the mailbox on the server is locked until **`quit()`** is called.

POP3.apop(*user*, *secret*)

Use the more secure APOP authentication to log into the POP3 server.

POP3.rpop(*user*)

Use RPOP authentication (similar to UNIX r-commands) to

log into POP3 server.

POP3.stat()

Get mailbox status. The result is a tuple of 2 integers: `(message count, mailbox size)`.

POP3.list([*which*])

Request message list, result is in the form `(response, ['mesg_num octets', ...], octets)`. If *which* is set, it is the message to list.

POP3.retr(*which*)

Retrieve whole message number *which*, and set its seen flag. Result is in form `(response, ['line', ...], octets)`.

POP3.dele(*which*)

Flag message number *which* for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

POP3.rset()

Remove any deletion marks for the mailbox.

POP3.noop()

Do nothing. Might be used as a keep-alive.

POP3.quit()

Signoff: commit changes, unlock mailbox, drop connection.

POP3.top(*which*, *howmuch*)

Retrieves the message header plus *howmuch* lines of the message after the header of message number *which*. Result is in form `(response, ['line', ...], octets)`.

The POP3 TOP command this method uses, unlike the RETR command, doesn't set the message's seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

POP3.uidl(*which=None*)

Return message digest (unique id) list. If *which* is specified, result contains the unique id for that message in the form `'response mesgnum uid`, otherwise result is list `(response, ['mesgnum uid', ...], octets)`.

POP3.utf8()

Try to switch to UTF-8 mode. Returns the server response if successful, raises **`error_proto`** if not. Specified in **RFC 6856** [https://datatracker.ietf.org/doc/html/rfc6856.html].

New in version 3.5.

POP3.stls(*context=None*)

Start a TLS session on the active connection as specified in **RFC 2595** [https://datatracker.ietf.org/doc/html/rfc2595.html]. This is only allowed before user authentication

context parameter is a **`ssl.SSLContext`** object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

This method supports hostname checking via **`ssl.SSLContext.check_hostname`** and *Server Name Indication* (see **`ssl.HAS_SNI`**).

New in version 3.4.

Instances of **`POP3_SSL`** have no additional methods. The interface of this subclass is identical to its parent.

POP3 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```
import getpass, poplib

M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list()[1])
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print(j)
```

At the end of the module, there is a test section that contains a more extensive example of usage.

`imaplib` — IMAP4 protocol client

Source code: Lib/imaplib.py [https://github.com/python/cpython/tree/3.11/Lib/imaplib.py]

This module defines three classes, `IMAP4`, `IMAP4_SSL` and `IMAP4_stream`, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in **RFC 2060** [https://datatracker.ietf.org/doc/html/rfc2060.html]. It is backward compatible with IMAP4 (**RFC 1730** [https://datatracker.ietf.org/doc/html/rfc1730.html]) servers, but note that the `STATUS` command is not supported in IMAP4.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

Three classes are provided by the `imaplib` module, `IMAP4` is the base class:

class imaplib.IMAP4(*host* = '', *port* = *IMAP4_PORT*, *timeout* = *None*)

> This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If *host* is not specified, `''` (the local host) is used. If *port* is omitted, the standard IMAP4 port (143) is used. The optional *timeout* parameter specifies a timeout in seconds for the connection attempt. If timeout is not given or is None, the global default socket timeout is used.
>
> The `IMAP4` class supports the `with` statement. When used

like this, the IMAP4 `LOGOUT` command is issued automatically when the **`with`** statement exits. E.g.:

```
>>> from imaplib import IMAP4
>>> with IMAP4("domain.org") as M:
...     M.noop()
...
('OK', [b'Nothing Accomplished. d25if65hy903weo.87'
```

Changed in version 3.5: Support for the **`with`** statement was added.

Changed in version 3.9: The optional *timeout* parameter was added.

Three exceptions are defined as attributes of the **`IMAP4`** class:

exception IMAP4.error

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

exception IMAP4.abort

IMAP4 server errors cause this exception to be raised. This is a sub-class of **`IMAP4.error`**. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

exception IMAP4.readonly

This exception is raised when a writable mailbox has its status changed by the server. This is a sub-class of **`IMAP4.error`**. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There's also a subclass for secure connections:

class imaplib.IMAP4_SSL(*host*='', *port*=*IMAP4_SSL_PORT*, *keyfile*=*None*, *certfile*=*None*, *ssl_context*=*None*, *timeout*=*None*)

This is a subclass derived from **`IMAP4`** that connects over an

SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If *host* is not specified, `''` (the local host) is used. If *port* is omitted, the standard IMAP4-over-SSL port (993) is used. *ssl_context* is a **`ssl.SSLContext`** object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

keyfile and *certfile* are a legacy alternative to *ssl_context* - they can point to PEM-formatted private key and certificate chain files for the SSL connection. Note that the *keyfile*/*certfile* parameters are mutually exclusive with *ssl_context*, a **`ValueError`** is raised if *keyfile*/*certfile* is provided along with *ssl_context*.

The optional *timeout* parameter specifies a timeout in seconds for the connection attempt. If timeout is not given or is None, the global default socket timeout is used.

Changed in version 3.3: *ssl_context* parameter was added.

Changed in version 3.4: The class now supports hostname check with **`ssl.SSLContext.check_hostname`** and *Server Name Indication* (see **`ssl.HAS_SNI`**).

Deprecated since version 3.6: *keyfile* and *certfile* are deprecated in favor of *ssl_context*. Please use **`ssl.SSLContext.load_cert_chain()`** instead, or let **`ssl.create_default_context()`** select the system's trusted CA certificates for you.

Changed in version 3.9: The optional *timeout* parameter was added.

The second subclass allows for connections created by a child process:

class imaplib.IMAP4_stream(*command*)

This is a subclass derived from **`IMAP4`** that connects to the `stdin/stdout` file descriptors created by passing *command*

to `subprocess.Popen()`.

The following utility functions are defined:

imaplib.Internaldate2tuple(*datestr*)

Parse an IMAP4 `INTERNALDATE` string and return corresponding local time. The return value is a **`time.struct_time`** tuple or `None` if the string has wrong format.

imaplib.Int2AP(*num*)

Converts an integer into a bytes representation using characters from the set `[A .. P]`.

imaplib.ParseFlags(*flagstr*)

Converts an IMAP4 `FLAGS` response to a tuple of individual flags.

imaplib.Time2Internaldate(*date_time*)

Convert *date_time* to an IMAP4 `INTERNALDATE` representation. The return value is a string in the form: `"DD-Mmm-YYYY HH:MM:SS +HHMM"` (including double-quotes). The *date_time* argument can be a number (int or float) representing seconds since epoch (as returned by **`time.time()`**), a 9-tuple representing local time an instance of **`time.struct_time`** (as returned by **`time.localtime()`**), an aware instance of **`datetime.datetime`**, or a double-quoted string. In the last case, it is assumed to already be in the correct format.

Note that IMAP4 message numbers change as the mailbox changes; in particular, after an `EXPUNGE` command performs deletions the remaining messages are renumbered. So it is highly advisable to use UIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

See also

Documents describing the protocol, sources for servers implementing it, by the University of Washington's IMAP Information Center can all be found at (**Source Code**) https://github.com/uw-imap/imap (**Not Maintained**).

IMAP4 Objects

All IMAP4rev1 commands are represented by methods of the same name, either upper-case or lower-case.

All arguments to commands are converted to strings, except for `AUTHENTICATE`, and the last argument to `APPEND` which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn't enclosed with either parentheses or double quotes) each string is quoted. However, the *password* argument to the `LOGIN` command is always quoted. If you want to avoid having an argument string quoted (eg: the *flags* argument to `STORE`) then enclose the string in parentheses (eg: `r'(\Deleted)'`).

Each command returns a tuple: `(type, [data, ...])` where *type* is usually `'OK'` or `'NO'`, and *data* is either the text from the command response, or mandated results from the command. Each *data* is either a `bytes`, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie: 'literal' value).

The *message_set* options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number (`'1'`), a range of message numbers (`'2:4'`), or a group of non-contiguous ranges separated by commas (`'1:3,6:9'`). A range can contain an asterisk to indicate an infinite upper bound (`'3:*'`).

An **`IMAP4`** instance has the following methods:

IMAP4.append(*mailbox*, *flags*, *date_time*, *message*)

Append *message* to named mailbox.

IMAP4.authenticate(*mechanism*, *authobject*)

Authenticate command — requires response processing.

mechanism specifies which authentication mechanism is to be used - it should appear in the instance variable `capabilities` in the form `AUTH=mechanism`.

authobject must be a callable object:

```
data = authobject(response)
```

It will be called to process server continuation responses; the *response* argument it is passed will be `bytes`. It should return `bytes` *data* that will be base64 encoded and sent to the server. It should return `None` if the client abort response `*` should be sent instead.

Changed in version 3.5: string usernames and passwords are now encoded to `utf-8` instead of being limited to ASCII.

IMAP4.check()

Checkpoint mailbox on server.

IMAP4.close()

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before `LOGOUT`.

IMAP4.copy(*message_set*, *new_mailbox*)

Copy *message_set* messages onto end of *new_mailbox*.

IMAP4.create(*mailbox*)

Create new mailbox named *mailbox*.

IMAP4.delete(*mailbox*)

Delete old mailbox named *mailbox*.

IMAP4.deleteacl(*mailbox*, *who*)

Delete the ACLs (remove any rights) set for who on mailbox.

IMAP4.enable(*capability*)

Enable *capability* (see **RFC 5161** [https://datatracker.ietf.org/doc/html/rfc5161.html]). Most capabilities do not need to be enabled. Currently only the `UTF8=ACCEPT` capability is supported (see **RFC 6855** [https://datatracker.ietf.org/doc/html/rfc6855.html]).

New in version 3.5: The **`enable()`** method itself, and **RFC 6855** [https://datatracker.ietf.org/doc/html/rfc6855.html] support.

IMAP4.expunge()

Permanently remove deleted items from selected mailbox. Generates an `EXPUNGE` response for each deleted message. Returned data contains a list of `EXPUNGE` message numbers in order received.

IMAP4.fetch(*message_set*, *message_parts*)

Fetch (parts of) messages. *message_parts* should be a string of message part names enclosed within parentheses, eg: `"(UID BODY[TEXT])"`. Returned data are tuples of message part envelope and data.

IMAP4.getacl(*mailbox*)

Get the `ACL`s for *mailbox*. The method is non-standard, but is supported by the `Cyrus` server.

IMAP4.getannotation(*mailbox*, *entry*, *attribute*)

Retrieve the specified `ANNOTATION`s for *mailbox*. The method is non-standard, but is supported by the `Cyrus` server.

IMAP4.getquota(*root*)

Get the `quota` *root*'s resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

IMAP4.getquotaroot(*mailbox*)

Get the list of `quota roots` for the named *mailbox*. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

IMAP4.list([*directory*[, *pattern*]])

List mailbox names in *directory* matching *pattern*. *directory* defaults to the top-level mail folder, and *pattern* defaults to match anything. Returned data contains a list of `LIST` responses.

IMAP4.login(*user*, *password*)

Identify the client using a plaintext password. The *password* will be quoted.

IMAP4.login_cram_md5(*user*, *password*)

Force use of `CRAM-MD5` authentication when identifying the client to protect the password. Will only work if the server `CAPABILITY` response includes the phrase `AUTH=CRAM-MD5`.

IMAP4.logout()

Shutdown connection to server. Returns server `BYE` response.

Changed in version 3.8: The method no longer ignores silently arbitrary exceptions.

IMAP4.lsub(*directory* = *'"'*, *pattern* = *'*'*)

List subscribed mailbox names in directory matching pattern. *directory* defaults to the top level directory and *pattern* defaults to match any mailbox. Returned data are tuples of message part envelope and data.

IMAP4.myrights(*mailbox*)

Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

IMAP4.namespace()

Returns IMAP namespaces as defined in **RFC 2342** [https://datatracker.ietf.org/doc/html/rfc2342.html].

IMAP4.noop()

Send `NOOP` to server.

IMAP4.open(*host*, *port*, *timeout*=*None*)

Opens socket to *port* at *host*. The optional *timeout* parameter specifies a timeout in seconds for the connection attempt. If timeout is not given or is None, the global default socket timeout is used. Also note that if the *timeout* parameter is set to be zero, it will raise a **`ValueError`** to reject creating a non-blocking socket. This method is implicitly called by the **`IMAP4`** constructor. The connection objects established by this method will be used in the **`IMAP4.read()`**, **`IMAP4.readline()`**, **`IMAP4.send()`**, and **`IMAP4.shutdown()`** methods. You may override this method.

Raises an auditing event `imaplib.open` with arguments `self`, `host`, `port`.

Changed in version 3.9: The *timeout* parameter was added.

IMAP4.partial(*message_num*, *message_part*, *start*, *length*)

Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

IMAP4.proxyauth(*user*)

Assume authentication as *user*. Allows an authorised administrator to proxy into any user's mailbox.

IMAP4.read(*size*)

Reads *size* bytes from the remote server. You may override this method.

IMAP4.readline()

Reads one line from the remote server. You may override this method.

IMAP4.recent()

Prompt server for an update. Returned data is `None` if no new messages, else value of `RECENT` response.

IMAP4.rename(*oldmailbox*, *newmailbox*)

Rename mailbox named *oldmailbox* to *newmailbox*.

IMAP4.response(*code*)

Return data for response *code* if received, or `None`. Returns the given code, instead of the usual type.

IMAP4.search(*charset*, *criterion*[, ...])

Search mailbox for matching messages. *charset* may be `None`, in which case no `CHARSET` will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error. *charset* must be `None` if the `UTF8=ACCEPT` capability was enabled using the **`enable()`** command.

Example:

```
# M is a connected IMAP4 instance...
typ, msgnums = M.search(None, 'FROM', '"LDJ"')

# or:
typ, msgnums = M.search(None, '(FROM "LDJ")')
```

IMAP4.select(*mailbox*='INBOX', *readonly*=*False*)

Select a mailbox. Returned data is the count of messages in *mailbox* (`EXISTS` response). The default *mailbox* is `'INBOX'`. If the *readonly* flag is set, modifications to the mailbox are not allowed.

IMAP4.send(*data*)

Sends `data` to the remote server. You may override this method.

Raises an auditing event `imaplib.send` with arguments `self`, `data`.

IMAP4.setacl(*mailbox*, *who*, *what*)

Set an `ACL` for *mailbox*. The method is non-standard, but is supported by the `Cyrus` server.

IMAP4.setannotation(*mailbox*, *entry*, *attribute*[, ...])

Set `ANNOTATION`s for *mailbox*. The method is non-standard, but is supported by the `Cyrus` server.

IMAP4.setquota(*root*, *limits*)

Set the `quota` *root*'s resource *limits*. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

IMAP4.shutdown()

Close connection established in `open`. This method is implicitly called by **`IMAP4.logout()`**. You may override this method.

IMAP4.socket()

Returns socket instance used to connect to server.

IMAP4.sort(*sort_criteria*, *charset*, *search_criterion*[, ...])

The `sort` command is a variant of `search` with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.

Sort has two arguments before the *search_criterion* argument(s); a parenthesized list of *sort_criteria*, and the searching *charset*. Note that unlike `search`, the searching *charset* argument is mandatory. There is also a `uid sort`

command which corresponds to `sort` the way that `uid search` corresponds to `search`. The `sort` command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.

This is an `IMAP4rev1` extension command.

IMAP4.starttls(*ssl_context=None*)

Send a `STARTTLS` command. The *ssl_context* argument is optional and should be a **`ssl.SSLContext`** object. This will enable encryption on the IMAP connection. Please read Security considerations for best practices.

New in version 3.2.

Changed in version 3.4: The method now supports hostname check with **`ssl.SSLContext.check_hostname`** and *Server Name Indication* (see **`ssl.HAS_SNI`**).

IMAP4.status(*mailbox*, *names*)

Request named status conditions for *mailbox*.

IMAP4.store(*message_set*, *command*, *flag_list*)

Alters flag dispositions for messages in mailbox. *command* is specified by section 6.4.6 of **RFC 2060** [https://datatracker.ietf.org/doc/html/rfc2060.html] as being one of "FLAGS", "+FLAGS", or "-FLAGS", optionally with a suffix of ".SILENT".

For example, to set the delete flag on all messages:

```
typ, data = M.search(None, 'ALL')
for num in data[0].split():
   M.store(num, '+FLAGS', '\\Deleted')
M.expunge()
```

Note

Creating flags containing ‘]’ (for example: “[test]”) violates **RFC 3501** [https://datatracker.ietf.org/doc/html/rfc3501.html] (the IMAP protocol). However, imaplib has historically allowed creation of such tags, and popular IMAP servers, such as Gmail, accept and produce such flags. There are non-Python programs which also create such tags. Although it is an RFC violation and IMAP clients and servers are supposed to be strict, imaplib nonetheless continues to allow such tags to be created for backward compatibility reasons, and as of Python 3.6, handles them if they are sent from the server, since this improves real-world compatibility.

IMAP4.subscribe(*mailbox*)

Subscribe to new mailbox.

IMAP4.thread(*threading_algorithm*, *charset*, *search_criterion*[, ...])

The `thread` command is a variant of `search` with threading semantics for the results. Returned data contains a space separated list of thread members.

Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

Thread has two arguments before the *search_criterion* argument(s); a *threading_algorithm*, and the searching *charset*. Note that unlike `search`, the searching *charset* argument is mandatory. There is also a `uid thread` command which corresponds to `thread` the way that `uid search` corresponds to `search`. The `thread` command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the matching messages threaded according to the specified threading algorithm.

This is an `IMAP4rev1` extension command.

IMAP4.uid(*command*, *arg*[, ...])

Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied; if none are provided, the server will return an error and an exception will be raised.

IMAP4.unsubscribe(*mailbox*)

Unsubscribe from old mailbox.

IMAP4.unselect()

`imaplib.IMAP4.unselect()` frees server's resources associated with the selected mailbox and returns the server to the authenticated state. This command performs the same actions as **`imaplib.IMAP4.close()`**, except that no messages are permanently removed from the currently selected mailbox.

New in version 3.9.

IMAP4.xatom(*name*[, ...])

Allow simple extension commands notified by server in `CAPABILITY` response.

The following attributes are defined on instances of **`IMAP4`**:

IMAP4.PROTOCOL_VERSION

The most recent supported protocol in the `CAPABILITY` response from the server.

IMAP4.debug

Integer value to control debugging output. The initialize value is taken from the module variable `Debug`. Values greater than three trace each command.

IMAP4.utf8_enabled

Boolean value that is normally `False`, but is set to `True` if

an **`enable()`** command is successfully issued for the `UTF8=ACCEPT` capability.

New in version 3.5.

IMAP4 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```
import getpass, imaplib

M = imaplib.IMAP4()
M.login(getpass.getuser(), getpass.getpass())
M.select()
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)')
    print('Message %s\n%s\n' % (num, data[0][1]))
M.close()
M.logout()
```

`smtplib` — SMTP protocol client

Source code: Lib/smtplib.py [https://github.com/python/cpython/tree/3.11/Lib/smtplib.py]

The `smtplib` module defines an SMTP client session object that can be used to send mail to any internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult **RFC 821** [https://datatracker.ietf.org/doc/html/rfc821.html] (Simple Mail Transfer Protocol) and **RFC 1869** [https://datatracker.ietf.org/doc/html/rfc1869.html] (SMTP Service Extensions).

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

class smtplib.SMTP(*host*='', *port*=0, *local_hostname*=None, [*timeout*,]*source_address*=None)

An `SMTP` instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional host and port parameters are given, the SMTP `connect()` method is called with those parameters during initialization. If specified, *local_hostname* is used as the FQDN of the local host in the HELO/EHLO command. Otherwise, the local hostname is found using `socket.getfqdn()`. If the `connect()` call returns anything other than a success code, an `SMTPConnectError` is raised. The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting

will be used). If the timeout expires, **TimeoutError** is raised. The optional source_address parameter allows binding to some specific source address in a machine with multiple network interfaces, and/or to some specific source TCP port. It takes a 2-tuple (host, port), for the socket to bind to as its source address before connecting. If omitted (or if host or port are `''` and/or 0 respectively) the OS default behavior will be used.

For normal use, you should only require the initialization/ connect, **sendmail()**, and **SMTP.quit()** methods. An example is included below.

The **SMTP** class supports the **with** statement. When used like this, the SMTP `QUIT` command is issued automatically when the **with** statement exits. E.g.:

```
>>> from smtplib import SMTP
>>> with SMTP("domain.org") as smtp:
...     smtp.noop()
...
(250, b'Ok')
>>>
```

All commands will raise an auditing event `smtplib.SMTP.send` with arguments `self` and `data`, where `data` is the bytes about to be sent to the remote host.

Changed in version 3.3: Support for the **with** statement was added.

Changed in version 3.3: source_address argument was added.

New in version 3.5: The SMTPUTF8 extension (**RFC 6531** [https://datatracker.ietf.org/doc/html/rfc6531.html]) is now supported.

Changed in version 3.9: If the *timeout* parameter is set to be zero, it will raise a **ValueError** to prevent the creation of a non-blocking socket

class smtplib.SMTP_SSL(*host*='', *port*=0, *local_hostname*=None, *keyfile*=None, *certfile*=None, [*timeout*,]*context*=None, *source_address*=None)

An **SMTP_SSL** instance behaves exactly the same as instances of **SMTP**. **SMTP_SSL** should be used for situations where SSL is required from the beginning of the connection and using **starttls()** is not appropriate. If *host* is not specified, the local host is used. If *port* is zero, the standard SMTP-over-SSL port (465) is used. The optional arguments *local_hostname*, *timeout* and *source_address* have the same meaning as they do in the **SMTP** class. *context*, also optional, can contain a **SSLContext** and allows configuring various aspects of the secure connection. Please read Security considerations for best practices.

keyfile and *certfile* are a legacy alternative to *context*, and can point to a PEM formatted private key and certificate chain file for the SSL connection.

Changed in version 3.3: context was added.

Changed in version 3.3: source_address argument was added.

Changed in version 3.4: The class now supports hostname check with **ssl.SSLContext.check_hostname** and *Server Name Indication* (see **ssl.HAS_SNI**).

Deprecated since version 3.6: keyfile and *certfile* are deprecated in favor of *context*. Please use **ssl.SSLContext.load_cert_chain()** instead, or let **ssl.create_default_context()** select the system's trusted CA certificates for you.

Changed in version 3.9: If the *timeout* parameter is set to be zero, it will raise a **ValueError** to prevent the creation of a non-blocking socket

class smtplib.LMTP(*host*='', *port*=*LMTP_PORT*, *local_hostname*=None, *source_address*=None[, *timeout*])

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It's common to use Unix sockets for LMTP, so our **connect()** method must support that as well as a regular host:port server. The optional arguments local_hostname and source_address have the same meaning as they do in the **SMTP** class. To specify a Unix socket, you must use an absolute path for *host*, starting with a '/'.

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don't support or require any authentication, but your mileage might vary.

Changed in version 3.9: The optional *timeout* parameter was added.

A nice selection of exceptions is defined as well:

exception smtplib.SMTPException

Subclass of **OSError** that is the base exception class for all the other exceptions provided by this module.

Changed in version 3.4: SMTPException became subclass of **OSError**

exception smtplib.SMTPServerDisconnected

This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the **SMTP** instance before connecting it to a server.

exception smtplib.SMTPResponseException

Base class for all exceptions that include an SMTP error code. These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in the **smtp_code** attribute of the error, and the **smtp_error** attribute is set to the error message.

exception smtplib.SMTPSenderRefused

Sender address refused. In addition to the attributes set by on all **SMTPResponseException** exceptions, this sets 'sender' to the string that the SMTP server refused.

exception smtplib.SMTPRecipientsRefused

All recipient addresses refused. The errors for each recipient are accessible through the attribute **recipients**, which is a dictionary of exactly the same sort as **SMTP.sendmail()** returns.

exception smtplib.SMTPDataError

The SMTP server refused to accept the message data.

exception smtplib.SMTPConnectError

Error occurred during establishment of a connection with the server.

exception smtplib.SMTPHeloError

The server refused our `HELO` message.

exception smtplib.SMTPNotSupportedError

The command or option attempted is not supported by the server.

New in version 3.5.

exception smtplib.SMTPAuthenticationError

SMTP authentication went wrong. Most probably the server didn't accept the username/password combination provided.

See also

RFC 821 [https://datatracker.ietf.org/doc/html/rfc821.html] - Simple Mail Transfer Protocol

Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

RFC 1869 **[https://datatracker.ietf.org/doc/html/rfc1869.html] - SMTP Service Extensions**

Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands, supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.

SMTP Objects

An **SMTP** instance has the following methods:

SMTP.set_debuglevel(*level*)

Set the debug output level. A value of 1 or `True` for *level* results in debug messages for connection and for all messages sent to and received from the server. A value of 2 for *level* results in these messages being timestamped.

Changed in version 3.5: Added debuglevel 2.

SMTP.docmd(*cmd*, *args* = '')

Send a command *cmd* to the server. The optional argument *args* is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, **SMTPServerDisconnected** will be raised.

SMTP.connect(*host* = 'localhost', *port* = 0)

Connect to a host on a given port. The defaults are to connect

to the local host at the standard SMTP port (25). If the hostname ends with a colon (`':'`) followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This method is automatically invoked by the constructor if a host is specified during instantiation. Returns a 2-tuple of the response code and message sent by the server in its connection response.

Raises an auditing event `smtplib.connect` with arguments `self, host, port`.

SMTP.helo(*name=''*)

Identify yourself to the SMTP server using `HELO`. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the **`helo_resp`** attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the **`sendmail()`** when necessary.

SMTP.ehlo(*name=''*)

Identify yourself to an ESMTP server using `EHLO`. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by **`has_extn()`**. Also sets several informational attributes: the message returned by the server is stored as the **`ehlo_resp`** attribute, **`does_esmtp`** is set to `True` or `False` depending on whether the server supports ESMTP, and **`esmtp_features`** will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use **`has_extn()`** before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by **`sendmail()`** when necessary.

SMTP.ehlo_or_helo_if_needed()

This method calls **`ehlo()`** and/or **`helo()`** if there has been

no previous `EHLO` or `HELO` command this session. It tries ESMTP `EHLO` first.

SMTPHeloError
: The server didn't reply properly to the `HELO` greeting.

SMTP.has_extn(*name*)
: Return **True** if *name* is in the set of SMTP service extensions returned by the server, **False** otherwise. Case is ignored.

SMTP.verify(*address*)
: Check the validity of an address on this server using SMTP `VRFY`. Returns a tuple consisting of code 250 and a full **RFC 822** [https://datatracker.ietf.org/doc/html/rfc822.html] address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

  Note

  Many sites disable SMTP `VRFY` in order to foil spammers.

SMTP.login(*user*, *password*, *, *initial_response_ok* = *True*)
: Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first. This method will return normally if the authentication was successful, or may raise the following exceptions:

  SMTPHeloError
  : The server didn't reply properly to the `HELO` greeting.

  SMTPAuthenticationError
  : The server didn't accept the username/password combination.

  SMTPNotSupportedError

The `AUTH` command is not supported by the server.

`SMTPException`
No suitable authentication method was found.

Each of the authentication methods supported by **`smtplib`** are tried in turn if they are advertised as supported by the server. See **`auth()`** for a list of supported authentication methods. *initial_response_ok* is passed through to **`auth()`**.

Optional keyword argument *initial_response_ok* specifies whether, for authentication methods that support it, an "initial response" as specified in **RFC 4954** [https://datatracker.ietf.org/doc/html/rfc4954.html] can be sent along with the `AUTH` command, rather than requiring a challenge/response.

Changed in version 3.5: **`SMTPNotSupportedError`** may be raised, and the *initial_response_ok* parameter was added.

SMTP.auth(*mechanism*, *authobject*, *, *initial_response_ok*=*True*)
Issue an `SMTP AUTH` command for the specified authentication *mechanism*, and handle the challenge response via *authobject*.

mechanism specifies which authentication mechanism is to be used as argument to the `AUTH` command; the valid values are those listed in the `auth` element of **`esmtp_features`**.

authobject must be a callable object taking an optional single argument:

data = authobject(challenge=None)

If optional keyword argument *initial_response_ok* is true, `authobject()` will be called first with no argument. It can return the **RFC 4954** [https://datatracker.ietf.org/doc/html/rfc4954.html] "initial response" ASCII `str` which will be encoded and sent with the `AUTH` command as below. If the `authobject()` does not support an initial response (e.g.

because it requires a challenge), it should return `None` when called with `challenge=None`. If *initial_response_ok* is false, then `authobject()` will not be called first with `None`.

If the initial response check returns `None`, or if *initial_response_ok* is false, `authobject()` will be called to process the server's challenge response; the *challenge* argument it is passed will be a `bytes`. It should return ASCII `str` *data* that will be base64 encoded and sent to the server.

The `SMTP` class provides `authobjects` for the `CRAM-MD5`, `PLAIN`, and `LOGIN` mechanisms; they are named `SMTP.auth_cram_md5`, `SMTP.auth_plain`, and `SMTP.auth_login` respectively. They all require that the `user` and `password` properties of the `SMTP` instance are set to appropriate values.

User code does not normally need to call `auth` directly, but can instead call the **`login()`** method, which will try each of the above mechanisms in turn, in the order listed. `auth` is exposed to facilitate the implementation of authentication methods not (or not yet) supported directly by **`smtplib`**.

New in version 3.5.

SMTP.starttls(*keyfile=None*, *certfile=None*, *context=None*)

Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call **`ehlo()`** again.

If *keyfile* and *certfile* are provided, they are used to create an **`ssl.SSLContext`**.

Optional *context* parameter is an **`ssl.SSLContext`** object; This is an alternative to using a keyfile and a certfile and if specified both *keyfile* and *certfile* should be `None`.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first.

Deprecated since version 3.6: keyfile and *certfile* are deprecated

in favor of *context*. Please use **ssl.SSLContext.load_cert_chain()** instead, or let **ssl.create_default_context()** select the system's trusted CA certificates for you.

SMTPHeloError
The server didn't reply properly to the HELO greeting.

SMTPNotSupportedError
The server does not support the STARTTLS extension.

RuntimeError
SSL/TLS support is not available to your Python interpreter.

Changed in version 3.3: context was added.

Changed in version 3.4: The method now supports hostname check with **SSLContext.check_hostname** and *Server Name Indicator* (see **HAS_SNI**).

Changed in version 3.5: The error raised for lack of STARTTLS support is now the **SMTPNotSupportedError** subclass instead of the base **SMTPException**.

SMTP.sendmail(*from_addr*, *to_addrs*, *msg*, *mail_options=()*, *rcpt_options=()*)

Send mail. The required arguments are an **RFC 822** [https://datatracker.ietf.org/doc/html/rfc822.html] from-address string, a list of **RFC 822** [https://datatracker.ietf.org/doc/html/rfc822.html] to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as 8bitmime) to be used in MAIL FROM commands as *mail_options*. ESMTP options (such as DSN commands) that should be used with all RCPT commands can be passed as *rcpt_options*. (If you need to use different ESMTP options to different recipients you have to use the low-level methods such as **mail()**, **rcpt()** and **data()** to send the message.)

Note

The *from_addr* and *to_addrs* parameters are used to construct the message envelope used by the transport agents. `sendmail` does not modify the message headers in any way.

msg may be a string containing characters in the ASCII range, or a byte string. A string is encoded to bytes using the ascii codec, and lone `\r` and `\n` characters are converted to `\r\n` characters. A byte string is not modified.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If `EHLO` fails, `HELO` will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will raise an exception. That is, if this method does not raise an exception, then someone should get your mail. If this method does not raise an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

If `SMTPUTF8` is included in *mail_options*, and the server supports it, *from_addr* and *to_addrs* may contain non-ASCII characters.

This method may raise the following exceptions:

`SMTPRecipientsRefused`

All recipients were refused. Nobody got the mail. The **`recipients`** attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

SMTPHeloError
The server didn't reply properly to the `HELO` greeting.

SMTPSenderRefused
The server didn't accept the *from_addr*.

SMTPDataError
The server replied with an unexpected error code (other than a refusal of a recipient).

SMTPNotSupportedError
`SMTPUTF8` was given in the *mail_options* but is not supported by the server.

Unless otherwise noted, the connection will be open even after an exception is raised.

Changed in version 3.2: msg may be a byte string.

Changed in version 3.5: `SMTPUTF8` support added, and **SMTPNotSupportedError** may be raised if `SMTPUTF8` is specified but the server does not support it.

SMTP.send_message(*msg*, *from_addr* = *None*, *to_addrs* = *None*, *mail_options* = *()*, *rcpt_options* = *()*)

This is a convenience method for calling **sendmail()** with the message represented by an **email.message.Message** object. The arguments have the same meaning as for **sendmail()**, except that *msg* is a `Message` object.

If *from_addr* is `None` or *to_addrs* is `None`, `send_message` fills those arguments with addresses extracted from the headers of *msg* as specified in **RFC 5322** [https://datatracker.ietf.org/doc/html/rfc5322.html]: *from_addr* is set to the *Sender* field if it is present, and otherwise to the *From* field. *to_addrs* combines the values (if any) of the *To*, *Cc*, and *Bcc* fields from *msg*. If exactly one set of *Resent-** headers appear in the message, the regular headers are ignored and the *Resent-** headers are used instead. If the message contains more than one set of *Resent-** headers, a **ValueError** is

raised, since there is no way to unambiguously detect the most recent set of *Resent-* headers.

`send_message` serializes *msg* using **`BytesGenerator`** with `\r\n` as the *linesep*, and calls **`sendmail()`** to transmit the resulting message. Regardless of the values of *from_addr* and *to_addrs*, `send_message` does not transmit any *Bcc* or *Resent-Bcc* headers that may appear in *msg*. If any of the addresses in *from_addr* and *to_addrs* contain non-ASCII characters and the server does not advertise `SMTPUTF8` support, an **`SMTPNotSupported`** error is raised. Otherwise the `Message` is serialized with a clone of its **`policy`** with the **`utf8`** attribute set to `True`, and `SMTPUTF8` and `BODY=8BITMIME` are added to *mail_options*.

New in version 3.2.

New in version 3.5: Support for internationalized addresses (`SMTPUTF8`).

SMTP.quit()

Terminate the SMTP session and close the connection. Return the result of the SMTP `QUIT` command.

Low-level methods corresponding to the standard SMTP/ESMTP commands `HELP`, `RSET`, `NOOP`, `MAIL`, `RCPT`, and `DATA` are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.

SMTP Example

This example prompts the user for addresses needed in the message envelope ('To' and 'From' addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered; this example doesn't do any processing of the **RFC 822** [https://datatracker.ietf.org/doc/html/rfc822.html] headers. In particular, the 'To' and 'From' addresses must be included in the message headers explicitly.

```
import smtplib

def prompt(prompt):
    return input(prompt).strip()

fromaddr = prompt("From: ")
toaddrs  = prompt("To: ").split()
print("Enter message, end with ^D (Unix) or ^Z (Windows)

# Add the From: and To: headers at the start!
msg = ("From: %s\r\nTo: %s\r\n\r\n"
       % (fromaddr, ", ".join(toaddrs)))
while True:
    try:
        line = input()
    except EOFError:
        break
    if not line:
        break
    msg = msg + line

print("Message length is", len(msg))

server = smtplib.SMTP('localhost')
server.set_debuglevel(1)
server.sendmail(fromaddr, toaddrs, msg)
server.quit()
```

Note

In general, you will want to use the **`email`** package's features to construct an email message, which you can then send via **`send_message()`**; see email: Examples.

`uuid` — UUID objects according to RFC 4122 [https://datatracker.ietf.org/doc/html/rfc4122.html]

Source code: Lib/uuid.py [https://github.com/python/cpython/tree/3.11/Lib/uuid.py]

This module provides immutable `UUID` objects (the `UUID` class) and the functions `uuid1()`, `uuid3()`, `uuid4()`, `uuid5()` for generating version 1, 3, 4, and 5 UUIDs as specified in RFC 4122 [https://datatracker.ietf.org/doc/html/rfc4122.html].

If all you want is a unique ID, you should probably call `uuid1()` or `uuid4()`. Note that `uuid1()` may compromise privacy since it creates a UUID containing the computer's network address. `uuid4()` creates a random UUID.

Depending on support from the underlying platform, `uuid1()` may or may not return a "safe" UUID. A safe UUID is one which is generated using synchronization methods that ensure no two processes can obtain the same UUID. All instances of `UUID` have an `is_safe` attribute which relays any information about the UUID's safety, using this enumeration:

class uuid.SafeUUID

New in version 3.7.

safe

The UUID was generated by the platform in a multiprocessing-safe way.

unsafe

The UUID was not generated in a multiprocessing-safe way.

unknown

The platform does not provide information on whether the UUID was generated safely or not.

class uuid.UUID(*hex=None*, *bytes=None*, *bytes_le=None*, *fields=None*, *int=None*, *version=None*, ***, *is_safe=SafeUUID.unknown*)

Create a UUID from either a string of 32 hexadecimal digits, a string of 16 bytes in big-endian order as the *bytes* argument, a string of 16 bytes in little-endian order as the *bytes_le* argument, a tuple of six integers (32-bit *time_low*, 16-bit *time_mid*, 16-bit *time_hi_version*, 8-bit *clock_seq_hi_variant*, 8-bit *clock_seq_low*, 48-bit *node*) as the *fields* argument, or a single 128-bit integer as the *int* argument. When a string of hex digits is given, curly braces, hyphens, and a URN prefix are all optional. For example, these expressions all yield the same UUID:

```
UUID('{12345678-1234-5678-1234-567812345678}')
UUID('12345678123456781234567812345678')
UUID('urn:uuid:12345678-1234-5678-1234-567812345678
UUID(bytes=b'\x12\x34\x56\x78'*4)
UUID(bytes_le=b'\x78\x56\x34\x12\x34\x12\x78\x56' +
              b'\x12\x34\x56\x78\x12\x34\x56\x78')
UUID(fields=(0x12345678, 0x1234, 0x5678, 0x12, 0x34
UUID(int=0x12345678123456781234567812345678)
```

Exactly one of *hex*, *bytes*, *bytes_le*, *fields*, or *int* must be given. The *version* argument is optional; if given, the resulting UUID will have its variant and version number set according to **RFC 4122** [https://datatracker.ietf.org/doc/html/rfc4122.html], overriding bits in the given *hex*, *bytes*, *bytes_le*, *fields*, or *int*.

Comparison of UUID objects are made by way of comparing their **`UUID.int`** attributes. Comparison with a non-UUID object raises a **`TypeError`**.

`str(uuid)` returns a string in the form `12345678-1234-5678-1234-567812345678` where the 32 hexadecimal digits represent the UUID.

`UUID` instances have these read-only attributes:

UUID.bytes

The UUID as a 16-byte string (containing the six integer fields in big-endian byte order).

UUID.bytes_le

The UUID as a 16-byte string (with *time_low*, *time_mid*, and *time_hi_version* in little-endian byte order).

UUID.fields

A tuple of the six integer fields of the UUID, which are also available as six individual attributes and two derived attributes:

Field	Meaning
`time_low`	the first 32 bits of the UUID
`time_mid`	the next 16 bits of the UUID
`time_hi_version`	the next 16 bits of the UUID
`clock_seq_hi_variant`	the next 8 bits of the UUID
`clock_seq_low`	the next 8 bits of the UUID
`node`	the last 48 bits of the UUID
`time`	the 60-bit timestamp
`clock_seq`	the 14-bit sequence number

UUID.hex

The UUID as a 32-character lowercase hexadecimal string.

UUID.int

The UUID as a 128-bit integer.

UUID.urn

The UUID as a URN as specified in **RFC 4122** [https://datatracker.ietf.org/doc/html/rfc4122.html].

UUID.variant

The UUID variant, which determines the internal layout of the UUID. This will be one of the constants **RESERVED_NCS**, **RFC_4122**, **RESERVED_MICROSOFT**, or **RESERVED_FUTURE**.

UUID.version

The UUID version number (1 through 5, meaningful only when the variant is **RFC_4122**).

UUID.is_safe

An enumeration of **SafeUUID** which indicates whether the platform generated the UUID in a multiprocessing-safe way.

New in version 3.7.

The **uuid** module defines the following functions:

uuid.getnode()

Get the hardware address as a 48-bit positive integer. The first time this runs, it may launch a separate program, which could be quite slow. If all attempts to obtain the hardware address fail, we choose a random 48-bit number with the multicast bit (least significant bit of the first octet) set to 1 as recommended in **RFC 4122** [https://datatracker.ietf.org/doc/html/rfc4122.html]. "Hardware address" means the MAC address of a network interface. On a machine with multiple network interfaces, universally administered MAC addresses (i.e. where the second least significant bit of the first octet is *unset*) will be preferred over locally administered MAC addresses, but with no other ordering guarantees.

Changed in version 3.7: Universally administered MAC addresses are preferred over locally administered MAC addresses, since the former are guaranteed to be globally unique, while the latter are not.

uuid.uuid1(*node=None*, *clock_seq=None*)

Generate a UUID from a host ID, sequence number, and the current time. If *node* is not given, `getnode()` is used to obtain the hardware address. If *clock_seq* is given, it is used as the sequence number; otherwise a random 14-bit sequence number is chosen.

uuid.uuid3(*namespace*, *name*)

Generate a UUID based on the MD5 hash of a namespace identifier (which is a UUID) and a name (which is a string).

uuid.uuid4()

Generate a random UUID.

uuid.uuid5(*namespace*, *name*)

Generate a UUID based on the SHA-1 hash of a namespace identifier (which is a UUID) and a name (which is a string).

The `uuid` module defines the following namespace identifiers for use with `uuid3()` or `uuid5()`.

uuid.NAMESPACE_DNS

When this namespace is specified, the *name* string is a fully qualified domain name.

uuid.NAMESPACE_URL

When this namespace is specified, the *name* string is a URL.

uuid.NAMESPACE_OID

When this namespace is specified, the *name* string is an ISO OID.

uuid.NAMESPACE_X500

When this namespace is specified, the *name* string is an X.500 DN in DER or a text output format.

The `uuid` module defines the following constants for the possible values of the **`variant`** attribute:

uuid.RESERVED_NCS
: Reserved for NCS compatibility.

uuid.RFC_4122
: Specifies the UUID layout given in **RFC 4122** [https://datatracker.ietf.org/doc/html/rfc4122.html].

uuid.RESERVED_MICROSOFT
: Reserved for Microsoft compatibility.

uuid.RESERVED_FUTURE
: Reserved for future definition.

See also

RFC 4122 [https://datatracker.ietf.org/doc/html/rfc4122.html] - A Universally Unique IDentifier (UUID) URN Namespace
: This specification defines a Uniform Resource Name namespace for UUIDs, the internal format of UUIDs, and methods of generating UUIDs.

Example

Here are some examples of typical usage of the **uuid** module:

```
>>> import uuid

>>> # make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

>>> # make a UUID using an MD5 hash of a namespace UUID
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

>>> # make a random UUID
>>> uuid.uuid4()
```

```
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

>>> # make a UUID using a SHA-1 hash of a namespace UUID
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9aee199e5d')

>>> # make a UUID from a string of hex digits (braces ar
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f

>>> # convert a UUID to a string of hex digits in standa
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

>>> # get the raw 16 bytes of the UUID
>>> x.bytes
b'\x00\x01\x02\x03\x04\x05\x06\x07\x08\t\n\x0b\x0c\r\x0e

>>> # make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
UUID('00010203-0405-0607-0809-0a0b0c0d0e0f')
```

`socketserver` — A framework for network servers

Source code: Lib/socketserver.py [https://github.com/python/cpython/tree/3.11/Lib/socketserver.py]

The `socketserver` module simplifies the task of writing network servers.

Availability: not Emscripten, not WASI.

This module does not work or is not available on WebAssembly platforms `wasm32-emscripten` and `wasm32-wasi`. See WebAssembly platforms for more information.

There are four basic concrete server classes:

class socketserver.TCPServer(*server_address*, *RequestHandlerClass*, *bind_and_activate* = *True*)

> This uses the internet TCP protocol, which provides for continuous streams of data between the client and server. If *bind_and_activate* is true, the constructor automatically attempts to invoke `server_bind()` and `server_activate()`. The other parameters are passed to the `BaseServer` base class.

class socketserver.UDPServer(*server_address*, *RequestHandlerClass*, *bind_and_activate* = *True*)

> This uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The parameters are the same as for `TCPServer`.

class socketserver.UnixStreamServer(*server_address*, *RequestHandlerClass*, *bind_and_activate* = *True*)
class socketserver.UnixDatagramServer(*server_address*, *RequestHandlerClass*, *bind_and_activate* = *True*)

These more infrequently used classes are similar to the TCP and UDP classes, but use Unix domain sockets; they're not available on non-Unix platforms. The parameters are the same as for **`TCPServer`**.

These four classes process requests *synchronously*; each request must be completed before the next request can be started. This isn't suitable if each request takes a long time to complete, because it requires a lot of computation, or because it returns a lot of data which the client is slow to process. The solution is to create a separate process or thread to handle each request; the **`ForkingMixIn`** and **`ThreadingMixIn`** mix-in classes can be used to support asynchronous behaviour.

Creating a server requires several steps. First, you must create a request handler class by subclassing the **`BaseRequestHandler`** class and overriding its **`handle()`** method; this method will process incoming requests. Second, you must instantiate one of the server classes, passing it the server's address and the request handler class. It is recommended to use the server in a **`with`** statement. Then call the **`handle_request()`** or **`serve_forever()`** method of the server object to process one or many requests. Finally, call **`server_close()`** to close the socket (unless you used a **`with`** statement).

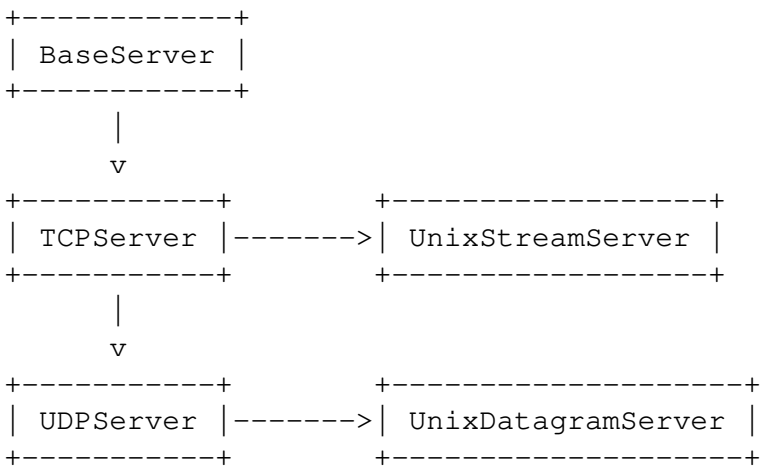
When inheriting from **`ThreadingMixIn`** for threaded connection behavior, you should explicitly declare how you want your threads to behave on an abrupt shutdown. The **`ThreadingMixIn`** class defines an attribute *daemon_threads*, which indicates whether or not the server should wait for thread termination. You should set the flag explicitly if you would like threads to behave autonomously; the default is **`False`**, meaning that Python will not exit until all threads created by **`ThreadingMixIn`** have exited.

Server classes have the same external methods and attributes, no

matter what network protocol they use.

Server Creation Notes

There are five classes in an inheritance diagram, four of which represent synchronous servers of four types:



Note that **`UnixDatagramServer`** derives from **`UDPServer`**, not from **`UnixStreamServer`** — the only difference between an IP and a Unix server is the address family.

class socketserver.ForkingMixIn
class socketserver.ThreadingMixIn

Forking and threading versions of each type of server can be created using these mix-in classes. For instance, **`ThreadingUDPServer`** is created as follows:

```
class ThreadingUDPServer(ThreadingMixIn, UDPServer)
    pass
```

The mix-in class comes first, since it overrides a method defined in **`UDPServer`**. Setting the various attributes also changes the behavior of the underlying server mechanism.

`ForkingMixIn` and the Forking classes mentioned below are only available on POSIX platforms that support **`fork()`**.

socketserver.ForkingMixIn.server_close() waits until all child processes complete, except if **socketserver.ForkingMixIn.block_on_close** attribute is false.

socketserver.ThreadingMixIn.server_close() waits until all non-daemon threads complete, except if **socketserver.ThreadingMixIn.block_on_close** attribute is false. Use daemonic threads by setting **ThreadingMixIn.daemon_threads** to `True` to not wait until threads complete.

Changed in version 3.7:
socketserver.ForkingMixIn.server_close() and **socketserver.ThreadingMixIn.server_close()** now waits until all child processes and non-daemonic threads complete. Add a new **socketserver.ForkingMixIn.block_on_close** class attribute to opt-in for the pre-3.7 behaviour.

class socketserver.ForkingTCPServer
class socketserver.ForkingUDPServer
class socketserver.ThreadingTCPServer
class socketserver.ThreadingUDPServer

These classes are pre-defined using the mix-in classes.

To implement a service, you must derive a class from **BaseRequestHandler** and redefine its **handle()** method. You can then run various versions of the service by combining one of the server classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses **StreamRequestHandler** or **DatagramRequestHandler**.

Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect

the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service "deaf" while one request is being handled – which may be for a very long time if a client is slow to receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class **`handle()`** method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor **`fork()`** (or where these are too expensive or inappropriate for the service) is to maintain an explicit table of partially finished requests and to use **`selectors`** to decide which request to work on next (or whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a long time (if threads or subprocesses cannot be used). See **`asyncore`** for another way to manage this.

Server Objects

class socketserver.BaseServer(*server_address*, *RequestHandlerClass*)

This is the superclass of all Server objects in the module. It defines the interface, given below, but does not implement most of the methods, which is done in subclasses. The two parameters are stored in the respective **`server_address`** and **`RequestHandlerClass`** attributes.

fileno()

Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to **`selectors`**, to allow monitoring multiple servers in the same process.

handle_request()

Process a single request. This function calls the following methods in order: **`get_request()`**, **`verify_request()`**, and **`process_request()`**. If the user-provided **`handle()`** method of the handler class raises an exception, the server's **`handle_error()`** method will be called. If no request is received within **`timeout`** seconds, **`handle_timeout()`** will be called and **`handle_request()`** will return.

serve_forever(*poll_interval=0.5*)

Handle requests until an explicit **`shutdown()`** request. Poll for shutdown every *poll_interval* seconds. Ignores the **`timeout`** attribute. It also calls **`service_actions()`**, which may be used by a subclass or mixin to provide actions specific to a given service. For example, the **`ForkingMixIn`** class uses **`service_actions()`** to clean up zombie child processes.

Changed in version 3.3: Added `service_actions` call to the `serve_forever` method.

service_actions()

This is called in the **`serve_forever()`** loop. This method can be overridden by subclasses or mixin classes to perform actions specific to a given service, such as cleanup actions.

New in version 3.3.

shutdown()

Tell the **`serve_forever()`** loop to stop and wait until it does. **`shutdown()`** must be called while **`serve_forever()`** is running in a different thread otherwise it will deadlock.

server_close()

Clean up the server. May be overridden.

address_family

The family of protocols to which the server's socket belongs. Common examples are **`socket.AF_INET`** and **`socket.AF_UNIX`**.

RequestHandlerClass

The user-provided request handler class; an instance of this class is created for each request.

server_address

The address on which the server is listening. The format of addresses varies depending on the protocol family; see the documentation for the **`socket`** module for details. For internet protocols, this is a tuple containing a string giving the address, and an integer port number: `('127.0.0.1', 80)`, for example.

socket

The socket object on which the server will listen for incoming requests.

The server classes support the following class variables:

allow_reuse_address

Whether the server will allow the reuse of an address. This defaults to **`False`**, and can be set in subclasses to change the policy.

request_queue_size

The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to **`request_queue_size`** requests. Once the queue is full, further requests from clients will get a "Connection denied" error. The default value is usually 5, but this

can be overridden by subclasses.

socket_type

The type of socket used by the server; **socket.SOCK_STREAM** and **socket.SOCK_DGRAM** are two common values.

timeout

Timeout duration, measured in seconds, or **None** if no timeout is desired. If **handle_request()** receives no incoming requests within the timeout period, the **handle_timeout()** method is called.

There are various server methods that can be overridden by subclasses of base server classes like **TCPServer**; these methods aren't useful to external users of the server object.

finish_request(*request*, *client_address*)

Actually processes the request by instantiating **RequestHandlerClass** and calling its **handle()** method.

get_request()

Must accept a request from the socket, and return a 2-tuple containing the *new* socket object to be used to communicate with the client, and the client's address.

handle_error(*request*, *client_address*)

This function is called if the **handle()** method of a **RequestHandlerClass** instance raises an exception. The default action is to print the traceback to standard error and continue handling further requests.

Changed in version 3.6: Now only called for exceptions derived from the **Exception** class.

handle_timeout()

This function is called when the `timeout` attribute has been set to a value other than `None` and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

process_request(*request*, *client_address*)

Calls `finish_request()` to create an instance of the `RequestHandlerClass`. If desired, this function can create a new process or thread to handle the request; the `ForkingMixIn` and `ThreadingMixIn` classes do this.

server_activate()

Called by the server's constructor to activate the server. The default behavior for a TCP server just invokes `listen()` on the server's socket. May be overridden.

server_bind()

Called by the server's constructor to bind the socket to the desired address. May be overridden.

verify_request(*request*, *client_address*)

Must return a Boolean value; if the value is `True`, the request will be processed, and if it's `False`, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns `True`.

Changed in version 3.6: Support for the context manager protocol was added. Exiting the context manager is equivalent to calling `server_close()`.

Request Handler Objects

class socketserver.BaseRequestHandler

This is the superclass of all request handler objects. It defines the interface, given below. A concrete request handler subclass must define a new **`handle()`** method, and can override any of the other methods. A new instance of the subclass is created for each request.

setup()

Called before the **`handle()`** method to perform any initialization actions required. The default implementation does nothing.

handle()

This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as **`self.request`**; the client address as **`self.client_address`**; and the server instance as **`self.server`**, in case it needs access to per-server information.

The type of **`self.request`** is different for datagram or stream services. For stream services, **`self.request`** is a socket object; for datagram services, **`self.request`** is a pair of string and socket.

finish()

Called after the **`handle()`** method to perform any clean-up actions required. The default implementation does nothing. If **`setup()`** raises an exception, this function will not be called.

class socketserver.StreamRequestHandler
class socketserver.DatagramRequestHandler

These **`BaseRequestHandler`** subclasses override the **`setup()`** and **`finish()`** methods, and provide **`self.rfile`** and **`self.wfile`** attributes. The **`self.rfile`** and **`self.wfile`** attributes can be read or written, respectively, to get the request data or return data to

the client. The **rfile** attributes support the **io.BufferedIOBase** readable interface, and **wfile** attributes support the **io.BufferedIOBase** writable interface.

Changed in version 3.6: **StreamRequestHandler.wfile** also supports the **io.BufferedIOBase** writable interface.

Examples

socketserver.TCPServer Example

This is the server side:

```
import socketserver

class MyTCPHandler(socketserver.BaseRequestHandler):
    """
    The request handler class for our server.

    It is instantiated once per connection to the server
    override the handle() method to implement communicat
    client.
    """

    def handle(self):
        # self.request is the TCP socket connected to th
        self.data = self.request.recv(1024).strip()
        print("{} wrote:".format(self.client_address[0])
        print(self.data)
        # just send back the same data, but upper-cased
        self.request.sendall(self.data.upper())

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999

    # Create the server, binding to localhost on port 99
    with socketserver.TCPServer((HOST, PORT), MyTCPHandl
```

```
        # Activate the server; this will keep running ur
        # interrupt the program with Ctrl-C
        server.serve_forever()
```

An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface):

```
class MyTCPHandler(socketserver.StreamRequestHandler):

    def handle(self):
        # self.rfile is a file-like object created by th
        # we can now use e.g. readline() instead of raw
        self.data = self.rfile.readline().strip()
        print("{} wrote:".format(self.client_address[0])
        print(self.data)
        # Likewise, self.wfile is a file-like object use
        # to the client
        self.wfile.write(self.data.upper())
```

The difference is that the `readline()` call in the second handler will call `recv()` multiple times until it encounters a newline character, while the single `recv()` call in the first handler will just return what has been sent from the client in one `sendall()` call.

This is the client side:

```
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) a
    # Connect to server and send data
    sock.connect((HOST, PORT))
    sock.sendall(bytes(data + "\n", "utf-8"))

    # Receive data from the server and shut down
```

```
    received = str(sock.recv(1024), "utf-8")

print("Sent:     {}".format(data))
print("Received: {}".format(received))
```

The output of the example should look something like this:

Server:

```
$ python TCPServer.py
127.0.0.1 wrote:
b'hello world with TCP'
127.0.0.1 wrote:
b'python is nice'
```

Client:

```
$ python TCPClient.py hello world with TCP
Sent:     hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent:     python is nice
Received: PYTHON IS NICE
```

`socketserver.UDPServer` Example

This is the server side:

```
import socketserver

class MyUDPHandler(socketserver.BaseRequestHandler):
    """
    This class works similar to the TCP handler class, e
    self.request consists of a pair of data and client s
    there is no connection the client address must be gi
    when sending data back via sendto().
    """

    def handle(self):
        data = self.request[0].strip()
```

```
        socket = self.request[1]
        print("{} wrote:".format(self.client_address[0])
        print(data)
        socket.sendto(data.upper(), self.client_address)

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999
    with socketserver.UDPServer((HOST, PORT), MyUDPHandl
        server.serve_forever()
```

This is the client side:

```
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# SOCK_DGRAM is the socket type to use for UDP sockets
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# As you can see, there is no connect() call; UDP has no
# Instead, data is directly sent to the recipient via se
sock.sendto(bytes(data + "\n", "utf-8"), (HOST, PORT))
received = str(sock.recv(1024), "utf-8")

print("Sent:     {}".format(data))
print("Received: {}".format(received))
```

The output of the example should look exactly like for the TCP server example.

Asynchronous Mixins

To build asynchronous handlers, use the **`ThreadingMixIn`** and **`ForkingMixIn`** classes.

An example for the **`ThreadingMixIn`** class:

```
import socket
```

```
import threading
import socketserver

class ThreadedTCPRequestHandler(socketserver.BaseRequest

    def handle(self):
        data = str(self.request.recv(1024), 'ascii')
        cur_thread = threading.current_thread()
        response = bytes("{}: {}".format(cur_thread.name
        self.request.sendall(response)

class ThreadedTCPServer(socketserver.ThreadingMixIn, soc
    pass

def client(ip, port, message):
    with socket.socket(socket.AF_INET, socket.SOCK_STREA
        sock.connect((ip, port))
        sock.sendall(bytes(message, 'ascii'))
        response = str(sock.recv(1024), 'ascii')
        print("Received: {}".format(response))

if __name__ == "__main__":
    # Port 0 means to select an arbitrary unused port
    HOST, PORT = "localhost", 0

    server = ThreadedTCPServer((HOST, PORT), ThreadedTCP
    with server:
        ip, port = server.server_address

        # Start a thread with the server -- that thread
        # more thread for each request
        server_thread = threading.Thread(target=server.s
        # Exit the server thread when the main thread te
        server_thread.daemon = True
        server_thread.start()
        print("Server loop running in thread:", server_t

        client(ip, port, "Hello World 1")
```

```
        client(ip, port, "Hello World 2")
        client(ip, port, "Hello World 3")

        server.shutdown()
```

The output of the example should look something like this:

```
$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3
```
